The same writer has sometimes known young clover, mown in the circumstances above mentioned; but this method, he thinks, would be prejudicial to the future growth of the crop, since the cutting off the stalks with the scythe must cause the juices to evaporate, and thereby weaken the stocks. One advantage there is however, he says, which attends this practice: namely, the removal of the stubble, which when very strong, and where the corn has been cut high, is apt to deaden the scythe at the mowing of the clover in the following summer, when cut for the general crop."

It has been remarked, that, "with some it is the custom to apply manure over the clover land immediately after the grain has been taken from the land, which in soils that are not in a good state of fertility, may be advantageous in preserving and invigorating the plants; but under other circumstances, it is not necessary. There is, however, another case in which the use of what is termed long stable dung, when not in the state of fermentation, may be found useful, by preventing the plants from being too closely nibbled and eaten up by sheep, which is that where the land is in the state of commonage or not inclosed. And the writer thinks, that, "when the clovers are to be continued for two or more years, the application of a thin coat of manure, in the autumn or spring season, is a practice from which great benefit may be derived, especially on lands that are in the less perfect state of heart. In the drier sorts of soil, this business may probably be done with the greatest advantage, about the latter end of February; but where the lands are soft, retentive of moisture, and poachy, the early part of the autumn, while the ground is sufficiently hard, may be the most suitable season for the purpose. Well rotted dung is perhaps the most proper in these cases." By performing the work at this period, "there is less danger," Mr. Middleton thinks, "of the clover plants dying away in the winter than is the case under other circumstances." At whatever season the manure may be applied, it should be spread out over the surface in as even a manner as possible, and be beaten perfectly fine.

In the county of Hertford, "it is a pretty common practice to sow coal ashes in the months of January or February, on such of the young clovers as are intended for mowing in the next summer. This is a very good practice where the land is not either fertile by nature, or much improved by the dung cart; but where the ground is in good heart, there remains little necessity for this top dressing on the clover: the method with the Hertfordshire husbandmen is to sow thirty bushels of coal ashes on an acre, which they often fetch ten or fifteen miles, and purchase at fourteen or fifteen pence per sack, for the purpose. Those fields of clover which are intended for pasturage, unless in very late and unkindly springs, will have attained a sufficient length to that purpose by the middle of April, and will afford store of valuable feed throughout the summer, but if it should be thought proper to reserve any part of this growth for seed, the cattle must be taken out, towards the latter end of May, or early in June; and it is much more eligible to feed down those fields which are intended for this purpose, in the fore part of the summer, than to take off the primary crop for hay, as such repeated mowings have a great tendency to impoverish the land, and to render it improper for sowing with wheat the next year: besides, in the former instance, the farmer is not confined to a set time for laying in the field, as the stock may be taken out at an early period of the summer; whereas this advantage is lost, when the first crop is reserved for hay, and thus a dry time may set in and stop the growth of the rowens, so that the crop of seed clover may be protracted till late in the autumn, when bad weather may be expected, which will greatly injure the sample," and produce other inconveniences.

As it is found that "clover will not perfect its seeds, if mown for that purpose early in the year; it is necessary to take off the first growth either by feeding or with the scythe, and to depend for the seed on those heads that are produced in the early autumn. Seed clover is found to turn out to good account in those years when the crops are not injured by the blast, which is often fatal to them, or by the rains in the autumn, which sometimes prove their destruction: for the time of harvesting this seed falling out late, when rainy weather may be expected, renders it on that account a very tedious job. But where the seed has headed well, is not affected by the blast, has been properly harvested, and the sample is unadulterated by the seeds of dock or other weeds, it proves a very lucrative article to the farmer, since it is no uncommon circumstance to grow a sack on an acre, and to sell it from thirty shillings to two guineas per bushel. And the trouble attending it is but trifling. It is found that a bushel of good clover seed, in kindly years, will weigh near 70lb. but in bad seasons it seldom rises higher than 65lb. Such clover seed as is of a deep purple colour, and is free from seeds of weeds of every kind, but more particularly of dock, which of all others is the most pernicious, fetches a price at market out of all proportion larger than that of an inferior kind, or where the sample is adulterated with other seeds. It is therefore of great consequence, at the laying in a piece of clover for seed, to be careful that the land be such that is not prone to blast, and that it be free from weeds of every description, the dock especially, as without this it is impossible to produce clean seed."

It is remarked by the author of the "Present State of Husbandry in Great Britain" that, "when it is proposed to

save

ſave the ſeeds of red clover, the firſt crop of graſs ſhould be cut early, ſo that the ſecond, whence the ſeeds are procured, may be ready for cutting by the end of Auguſt, or beginning of September. The reaſon of making choice of the ſecond crop, is, he ſays, that it always branches out into more ſeed-bearing plants, or ſtalks, than the firſt crop, and conſequently a greater quantity of ſeed is procured from the ſame extent of land. Beſides, the hay of a firſt crop of clover, is more valuable than that of the ſecond; and as it is neceſſary to thraſh clover-hay very much, in order to ſeparate the huſks in which the ſeeds are incloſed from the ſtems, or ſtalks, the loſs of hay is, of courſe, leſs conſiderable in the one caſe, than it would be in the other, while the crop of ſeed is at the ſame time more abundant. A crop of clover, of which it is propoſed to ſave the ſeeds, ſhould, he thinks, be allowed to ſtand till the huſks become quite brown, and the ſeeds have acquired a degree of firmneſs. It ſhould then be cut, and harveſted in every reſpect like other hay; and the ſeeds thraſhed out at any period during the following winter, or ſpring, according to the farmer's convenience. The quantity, he ſays, commonly reaped, is from four to five buſhels the Engliſh acre; weighing, when thoroughly clean, from two to three hundred weight. The expence of thraſhing is, he ſays, conſiderable—not leſs than from 5*s.* 6*d.* to 7*s.* the buſhel. This great expence, which, from the laborious nature of the work, cannot be reduced while the operation continues to be performed by manual labour, may, he hopes, ſoon induce ſome intelligent mechanic to conſtruct a machine, by which the labour may be greatly leſſened, while the work may be as completely, and more expeditiouſly performed." See Clover *Threſhing-Machine.*

It has been ſtated that "the principal objections to the feeding of clover crops, are thoſe of their uncertainty, on account of the ſtate of the ſeaſon at which they become ripe, the trouble and expence of threſhing out the ſeed, and the injury which they produce in leſſening the fertility of the ſoil. The high value of the ſeed, in moſt ſeaſons, is however, he obſerves, a great inducement to the letting of clover crops ſtand for that purpoſe." And froſty nights, and hot, ſunny, dry days in May, are very prejudicial, Mr. Banniſter ſays, to the clovers, and prevent a ſucceſſion in the growth of thoſe which have been eaten down, as doth likewiſe dry and ſultry weather in June; ſo that in backward ſprings and hot ſummers the clovers produce but a trifling return either for feeding or hay, when compared to the growth of thoſe years wherein the ſprings and ſummers have been more kindly and propitious. During the weather above mentioned, the ſtalk and leaves are often ſo totally ſcorched, that he has known in the fields of this graſs, when advanced to ſome height, ſo as to have formed the heads for bloom, and to promiſe fair for a crop, that the leaves have univerſally dropt off, and the juices have been ſo much exhauſted by the parching heat of the ſun, that the utter deſtruction of the crop has enſued. When this diſaſter happens, and the weather continues dry and ſultry till the middle of June, the beſt way is to ſet on the mowers, without waiting any longer in expectation of rain, and to truſt to future ſhowers for improving the lattermath. But although on thin lands, ſuch as gravels, chalks, &c. the clovers are often ruined by a hot and parching ſummer, yet on loams there is not that danger to be apprehended from this contingency, as theſe grounds, being of a ſtronger nature, will puſh on the clovers with greater vigour in their progreſs. This diſpoſition in the clovers to burn in a dry ſummer on thin ſoils, ſhows the neceſſity of laying them in early for the ſcythe, and ſtrongly enforces the rule before recommended, not to winter feed this graſs with cattle of any kind after Chriſtmas. Clover begins to form its head for bloom towards the middle of June, and will continue in a growing ſtate till it becomes in full bloſſom, at which time it is in the higheſt perfection to mow for hay; but this graſs differs in this particular from ſaintfoin, that, when its bloſſoms are fully expanded, they continue much longer in that ſtate than the laſt-mentioned graſs, ſo that if the weather ſhould prove wet and unkindly for the haying, the clovers will wait a fortnight, after they become in bloſſom, without ſuſtaining any material injury, either by the ſhedding of the leaf or bloom; for the ſame weather which renders it improper to mow this graſs, continues it in a growing ſtate, and prevents the bloſſom from dying away. When the crops of clover are large and heavy, it is neceſſary that the ſwaths ſhould be turned over at the making, the ſtalks of this graſs being very replete with juices. This may be done the next day after the mowing, or the ſecond day after, as the weather is more or leſs favourable, obſerving that, as the chief virtue of this hay reſides in the leaf and bloſſom, the leſs theſe are diſturbed the more valuable will be the fodder; on which account the tedding of this hay abroad, as is practiſed by ſome people, cannot fail to be of the greateſt injury. From the wind-rows it ſhould be made up into graſs cocks, which, having enjoyed the influence of the ſun and air for a day or two, may be thrown into large cocks for carting. But if wet weather prevails during the ſeaſon for making this hay, it cauſes an infinite deal of trouble to the farmer, and the clover, from having been frequently ſhaken abroad, is deprived of its moſt nutritious particles, namely, the bloſſom and the leaf of the plants. See Hay-*making.*

The ſame author ſtates further, that "there is an accident which ſometimes happens to young clovers that cuts off all hopes of a crop, and obliges the farmer to plough up his land for wheat. This malady takes its riſe from a worm which gnaws off the graſs juſt within the ground, ſo that the blade withers and dies away. A gentleman of great knowledge and experience in every article that relates to country affairs, aſſured him that, in December 1777, he had ſuffered very conſiderably from this inſect, which in the preceding ſummer totally deſtroyed ſeveral acres of clover on his farm, and that this happened on the beſt of his land, worth more than 20*s.* per acre, whilſt that of inferior goodneſs, and thoſe fields which worked badly at feed time, eſcaped the diſaſter." It is obſerved that "clover is rarely ſuffered to continue longer on the ground than one year; after which the field is generally ſown with wheat at one ploughing, a mode of huſbandry exceedingly advantageous to the farmer, who thereby enjoys a crop during the fallow year, that yields him conſiderable profit, and leaves the ground in far better condition for wheat, than would have been the cleaneſt and beſt conducted fallow, there being no preparation ſo kindly for this grain as clover hay. It has been long ſince remarked, and every year's experience confirms the truth of the obſervation, that clover lays, which have been mown the preceding ſummer, do uniformly produce better crops of wheat, *cæteris paribus*, than thoſe which were depaſtured: whereas, on the firſt idea, one ſhould ſuppoſe the contrary would be the event, from a conſideration that the ſurface of the paſture had been improved by the dung of the cattle which fed on it. This preference in favour of the mown clover, he is inclined to think, ariſes partly from the ſhedding of the leaf, which acts as a manure to the ground, but it is chiefly owing to the ſhade which the land enjoyed, during the ſummer, from the ſcorching heat of the ſun, by which the nutritious particles were retained; whereas the field, which had been fed down cloſe, could participate of neither of theſe benefits;

and

and, with reſpect to the dung of the cattle, the moiſture of other nutritious matters having been exhaled by the ſun, but ſmall advantages could be derived from it. But thoſe who keep folding flocks generally begin to plough up their clover lays early in the ſummer, and having ploughed one day's work, ſet the fold on that part; and the whole of this ploughed ground being gone over by the ſheep, another journey is to be ploughed; and which buſineſs of ploughing and folding is to be continued till Michaelmas, when the whole field is to be broken up. By thus ploughing up the field at various times, a portion of feed is reſerved for the ſtock ſo long as the clover continues to grow, and the major part of it may be ploughed up ſome conſiderable time before the wheat ſeaſon, whereby the ground becomes ſufficiently cloſed, ſo as to guard againſt the ill effects of the worm: and this end is ſtill more eſſentially anſwered by the folding, which never fails to be of great advantage, and which he is inclined to think proceeds rather from the treading of the ſheep, whereby the ground is compreſſed to a texture more firm and compact, than from any virtue in their dung and urine, which can be of no material uſe in the heat of the ſummer: but when, after ſeed time, the ſheep are folded on the ground, this is undoubtedly of infinite ſervice, the invigorating moiſture of the dung and urine of the ſheep, being immediately waſhed down to the roots of the grain; for which reaſon this manner of folding claims a decided preference over all others, ſo long as the weather will admit of its being purſued with propriety.

The clover crops are often mown as a green fodder for the horſes in the ſummer, which purpoſe it anſwers extremely well, and, if the land on which it is raiſed be in good condition, will, in a kindly ſpring, be fit for the ſcythe ſome time within the month of May, and may be cut twice for this uſe; or the ſecond crop may be ſuffered to ſtand for ſeed, or be fed off, according as the farmer's exigencies may require. But ſince the culture of lucerne hath been brought into general practice, few farmers chooſe to be without a field of that valuable graſs, which in this reſpect has greatly the advantage of clover, being not only equally wholeſome and nutritious, but on good land may be mown three or four times in the courſe of the ſummer, and will remain many years on the ground. See Lucerne.

It has been remarked by a late writer, that though much advantage may be derived from the converting of clover crops into hay, and letting them remain for ſeed, it is probable that a ſtill greater benefit may be produced by the practice of cutting the crops green, occaſionally, as they attain a ſufficient growth; and conveying them, when wanted, to the horſes or other cattle, in the ſtables and fold-yards, in order to their being conſumed in the ſtalls. It is contended, he ſays, by an experienced agriculturer, that in this manner it will certainly ſupport more than twice the ſtock it would do, if fed off upon the ground where it grew; and the additional quantity of manure that will by this method be made in the ſtalls and yards, if they are kept well littered with any ſort of ſtraw, or even ruſhes or fern, will fully compenſate the farmer for this expence in cutting and bringing the clover into the yards. In caſes where lucerne cannot be grown to advantage, this may, without doubt, be the caſe.

It is ſuggeſted, that it is a method which experience, in many parts of the kingdom, has proved to be of the greateſt advantage, eſpecially where the buſineſs is not upon too extenſive a ſcale; but in large concerns, it is, perhaps, impoſſible to attend to it ſo fully as may be neceſſary for deriving the greateſt benefit from it. The reſult of an experiment ſtated by a writer of conſiderable accuracy, however, he ſays, ſhows, that even on an extenſive ſcale it is a practice which is attended with vaſt advantage. "In this trial ſeven acres of clover, cut green, were found to be ſufficient for twenty horſes, ſeven cows, five calves, and five pigs, for the period of ſeventeen weeks from the middle of May. They were fed in the ſtable and rick-yard, being taken twice in the day to water, and the horſes had neither hay nor corn." And in calculating the value of the crop, it is remarked that the horſes could not have been kept equally well for leſs than eight-pence a day; but as the uſual price at which they are taken in at, in that diſtrict, is two ſhillings and ſixpence the week, it may be better to take that as the principle of calculation.

20 Horſes, 17 weeks, at 2*s.* 6*d.* per week	42*l.*	10*s.*	0*d.*
7 Cows, - ditto, at 2*s.* 6*d.* per week	14	17	6
5 Calves, - ditto, at 1*s.* 6*d.* per week	6	7	6
5 Pigs, - ditto.	0	0	0
	£63	15	0
Or, per acre,	9	2	1

And, "the quantity of dung raiſed by the above ſtock, is ſuppoſed to be from four to five hundred loads, which is eſtimated at 2*s.* 6*d.* per load." But "the expence in labour for cutting and conveying the food to the ſtock, is not charged; which renders the experiment in ſome meaſure incomplete. The benefit of the practice is, however, fully eſtabliſhed." And the great ſuperiority and utility of this practice are exhibited in a ſtill more ſtriking point of view, by contraſting this with the conſumption of the ſame ſort of crop in the field, by an equal number of the ſame kinds of ſtock; as, in the time five acres had been uſed in the former method, thirty had been conſumed in the latter, and the horſe part of the ſtock left in much worſe condition. And it is added, that, "beſides the ſuperiority of the practice of ſoiling this ſort of crop in the economy of food, it has the important advantage, as has been ſeen, of affording much larger ſupplies of manure, eſpecially where the ſtalls and fold-yards are kept occaſionally well bedded and cleaned up, as the converſion of the materials proceeds, which muſt be greatly expedited from the vaſt increaſe in the urinary, as well as other diſcharges that muſt of neceſſity take place in this ſort of feeding.

The principal difference between feeding clovers off, on the land, and conſuming them in their green ſtate, in this manner, is ſuppoſed by Mr. Kent to be this; "the quick growth of the graſs, after mowing, ſhades the ground, and prevents the ſun from exhaling the moiſture of the land, ſo much as it would if fed bare; conſequently it continues to ſpring with more vigour; and the moment one crop is off another begins to ſhoot up. Whereas, when cattle feed it, they frequently deſtroy as much as they eat, and, beſides, bruiſe the necks of the roots with their feet, which prevents the clover from ſpringing ſo freely as it does after a clean cut by the ſcythe. In hot weather, which is the common ſeaſon for feeding clover, the flies too are generally ſo troubleſome to the cattle, that they are continually running from hedge to hedge to bruſh them off; by which it is inconceivable what injury they do to the crop. But when they are fed in ſtalls and yards they are more in the ſhade; they thrive better, and, at the ſame time, conſume the whole of what is given them without waſte." The author of "Practical Agriculture," however, remarks on this, that "though much of the ſucceſs attending this practice without doubt depends on theſe circumſtances, yet that the upper parts of the roots are leſs penetrated by moiſture, and fewer of the plants of course destroyed." He adds, that "by proper attention to this crop a very useful and abundant green food, for different sorts of live stock, may be provided at an early period of the spring, especially when the winters are not very severe." And it is advised by Mr. Middleton, "on the poorer sort of soils to have both the first and second crops of this plant to be eaten green upon the land by sheep and bullocks, being mown and given them to feed upon." In this way the cattle thrive better from their filling themselves sooner, and having more rest; and there is no waste. But in order to derive the greatest possible advantage from the soiling with this or other crops, convenient covers, sheds, or other suitable houses are necessary to be provided. See SOILING.

It is remarked, in addition, however, "that the practice of feeding down or pasturing clover crops with live stock, though it may be advantageous in many cases, especially where sheep-husbandry forms a principal object, always requires to be conducted with care and attention, both in respect to the plants and the animals that are to feed upon them." As from the tender nature of the clover plant it should seldom be eaten on the land by the heavier sorts of cattle, because, from the greedy manner in which they feed, many of the plants are pulled up, and others, as has been seen, greatly injured or destroyed by being bruised in their treading, especially as they protrude their young shoots. Horses are particularly objected to on this account by Mr. Parkinson. The most appropriate sort of stock is obviously that of sheep; but where the soils are of the drier kind, the lighter sorts of stock of other descriptions may be occasionally admitted, such as calves, foals, and young beasts. And, as pigs are fond of the clover plant, and thrive well upon it, they may sometimes be admitted with advantage. In the practice of lamb-suckling, it is an useful application of the young clovers to turn the ewes upon them, as they afford a sort of pasturage, which has much effect in increasing the flow of milk. They may, likewise, in the opinion of the author of the "Report of Middlesex," be applied to the fattening of sheep in April and May; and be fed by the sheep intended for turnips, in the autumn, till they are ready, with much profit and advantage. No sort of stock should, however, be kept upon crops of clover where the land is soft, wet, or poachy. Mr. Marshall says, that, in some of the southern districts, where it is the custom to eat down the young clovers by sheep, it is usual to choose a dry season for the purpose, the stock being removed in case the land becomes soft and wet. When this sort of stock is employed, it may be the most safe practice not to permit the animals to continue too long upon the land; as by eating the plants too closely they may sustain much mischief. It is contended by some, that treading the soil lightly where the lands are dry, may be of great utility to the clover plants, by forcing the earth to the roots, and in that way protecting and rendering them more capable of resisting the effects of frost in the winter season. It has likewise been suggested, that "the eating off the weak lateral shoots that were thrown out while under the shade of the grain crops, may be serviceable by increasing the strength of the plants, and enabling them to withstand the frosts, as well as to shoot more strongly in the spring." It may, therefore, be concluded that the most beneficial method, where the pasturing of this crop, either in the spring or autumn, is had recourse to, is not to suffer the lands to be fed upon when in a moist state, or to be too hard stocked, or with the heavier sort of animals, at any time while they remain upon it.

In the feeding down this sort of crops, as has been already seen, there is not only danger of injuring the plants, but the animals that consume them. Without proper management, cattle and other animals, on being turned upon them, often suffer great inconvenience, and are in danger of being destroyed by the vast distension of their stomachs which takes place. In this situation, the animals are, in the language of the farmer, said to be *blown* or *hoven*. The nature of the disease does not seem to be much investigated; but it probably arises in consequence of the large quantity of green succulent herbage being greedily devoured without due mastication, by which it undergoes an uncommon degree of fermentation in the stomach; and from this sudden decomposition, an unusual quantity of gaseous fluid, or *flatus*, is at once set at liberty, which ultimately overcomes the contractile power of the digestive organ, and the animal is destroyed. The supposition is rendered more probable from the circumstance of the affection being less apt to take place when the clovers or other similar herbage are fed upon in a dry state, as the stock in these cases are not able to consume them in so expeditious a manner, or in so large a proportion. It is added, that on these principles the practice of not suffering the cattle, or other sorts of stock, to feed upon them when they are wet, and there is a full bite, would seem to be perfectly correct. The advice of not turning the animals upon the crops before the sun dissipated the dew and moisture deposited in the night, is likewise judicious, and ought to be attended to, as well as that of keeping them in motion as much as possible when first turned in. With sheep the same precautions may be necessary, if they be put upon them with the other stock in their full growth; but when they are turned in after they have in some degree been fed down, there will be little danger of their being injured. Where the clovers are eaten off, as after-grass, in their soft, foggy, and young state of growth, there is, however, great danger of the stock being hurt in this way, unless these circumstances be attended to and carefully guarded against. See HOVEN.

It is observed to be the practice with some "when the land is intended for the purpose of early pasturage, and in some cases where the object is hay, to sow rye, rib, and other similar grasses with the clover. In the first intention the practice may be beneficial, as the rye grass rises early, and may contribute to afford a more full and better herbage for the stock at such periods, especially on the better sorts of soil; but with the latter view it should perhaps seldom be made use of, as the clover will in general produce a sufficiently abundant crop of itself; and from other sorts of plants being mixed with it, on account of their drying in an unequal manner, it may sustain injury as hay. It is probably, for some reason of this sort, that such clover-hay as is mixed with other grasses is less saleable, and of considerably less value in the London markets, than that which consists solely of clover. Some cultivators, however, suppose, that by blending rye-grass with clover in a small proportion, a strength and body is given to the crop." And it has been suggested as an improvement where rye grass is mixed with clover, to sow the latter a week or two before the other, as from the clover plants having a tender, weak stem in their early growth, they may in that way be prevented from being injured by those of the rye-grass clasping round and shading them. But when the crop is designed for cutting green for the purpose of soiling animals, it would seem to be the best method not to sow any other sort of grass with it, as no advantage can be gained in that way, while there may be danger of the crops being injured by it.

It is obvious, that "the chief disadvantage of this almost invaluable plant, is that of the shortness of its abiding or continuing in the lands, especially in those of the lighter and more free kinds, as hinted above. It is asserted by some, not to laft longer than two years, except on grounds that are perfectly frefh; and, in fome cafes, where it has been often repeated, not more than once. According to Mr. Marfhall, in fome of the fouthern counties, it is, however, found more durable on the calcareous foils, efpecially where not frequently repeated on the fame land, from its being better able to contend with weeds in its natural ftate of growth. Thefe facts fhow the neceffity of keeping it as far diftant as poffible in the courfes of cropping, efpecially on all the more light friable forts of foil, and the fuperior advantages of cultivating it on thofe of the calcareous kinds." And it is fuggefted as probable, that "its duration may be confiderably prolonged, by preventing the plants from fhooting up to feed ftems as much as poffible, either by keeping them cut by the fcythe, or by the feeding them down by ftock in a moderate degree, as in thefe ways they will be prevented from being fo foon exhaufted in their roots, as happens in many other forts of plants, as soon as they have perfected their feeds.

It is obferved in the "Hertford Survey on Agriculture," that the beft farmers about Ware mow the firft growth, and always feed the fecond: they confider it as good management to mow the firft, as it is, in their eftimation, bad to mow the fecond. However, he faw feveral fecond crops in full bloffom between Walkern and Stevenage, of a luxuriance that fpoke no bad management: nor is it a point at all to be afcertained. The practice of various other diftricts is in favour of mowing both. And Mr. Whittington has no doubt upon this point, thinking that better wheat will be after two mowings than after one. About Hatfield, and all that vicinity, they have cultivated clover fo long and fo repeatedly, that the foil is, as the farmers fay, fick of the plant. It matters not how fine a crop may be in autumn, it dies even fo late as in that month. Mr. Keate had a proof of the benefit of not fowing it in one or two courfes confecutively. Having part of a field for five or fix years under lucerne, when it was broken up, barley and clover were fown over the part which had been under lucerne, and alfo on a contiguous piece, where the clover-hufbandry had not been interrupted on the latter, the clover in 1801 failed and was ploughed up, but where the lucerne had grown, the clover was, as the writer faw, extremely fine, thick, and regular. This fhows, he thinks, that other graffes may be fubftituted, and yet the land refrefhed and prepared for future clover without a failure. The great price which hay has yielded of late years, has been an injury to the land; the farmers have been unwilling to vary the courfe, or to plough up a bad plant; and very foul fields are the confequence. Others finding clover crops apt to fail fow trefoil alfo. And this variation of trefoil is excellent management in his opinion.

It is added, that Mr. Clarke of Sandridgbury has had no clover fail till laft year, (1800.) If he intends feeding, he mixes trefoil, otherwife he fows clover alone. He mows fome twice for hay; fome once, and then feeds fheep on the land. His beft wheat is after two mowings, one for hay, and the fecond for feed; this he attributes to the great fall of the leaf, and to the plants covering the foil from the fun fo well and fo long. And Mr. Biggs, near St. Alban's, grows better wheat after mowing than after feeding; and better after two mowings than one, and this general fuperiority has, in his opinion, amounted to four or five bufhels an acre. And many others reap better wheat after mowing than after feeding the clover. And fome think, that the reafon is "the clover's being fed too clofe: were it kept to a confiderable growth before it were turned in, fo that all fhould not be eaten, but enough trod down to cover the land from the fun, then feeding would give the beft wheat." And in Norfolk, it is remarked, by the author of the report of that diftrict, that thirty years ago they had for fome time found their clover crop failing, from its recurring too often; this caufed the variation of fubftituting trefoil for one round, and the clover being fown but once in nine years, the evil was removed. And he now found the fame account every where in the fouth of the country, that the land (whatever the foil), was what they call fick of clover. Formerly it was fown every fourth or fifth year; but now if it returns fo often it fails for acres together; they therefore fow clover in one round, and then fubftitute white clover and trefoil, adding a little ray grafs, but as little as they can help. Whether the wheat is as good after thefe feeds as after clover, is rather an unfettled point. From Mr. Burton, a moft intelligent obferver upon this queftion, the writer found that he himfelf got as good wheat after white Dutch as after red clover, but that he believed the true change for the foil would be to fow no feeds at all; and he fhowed him a large field of red clover, part of which was very regular and good, and part inferior, the former was in a courfe where no feeds had been fown, and the latter where Dutch and trefoil were introduced: a ftrong confirmation of his remark. Mr. Fowel ufes fix pecks of ray, fix pounds of clover or trefoil, and four of white clover for two years.

And the land round Hingham is tired of producing this crop, and caufes the variation of fowing ray, trefoil, and white clover.

It is alfo obferved, that in Happing-hundred, they admit at Catfield, that "if clover recurs too often the land will not yield it, but their method is not an alternate fubftitution of other feed, or baulking the land for a round, but to take a fix courfe fhift inftead of a five, and mixing white clover and trefoil and ray, by which two precautions they fucceed well.

Thefe ftatements from different parts of the county clearly fhow the neceffity of caution in repeating crops of clover on moft forts of foil.

It may be obferved, that fince red clover has been cultivated in England, great improvements have been made in heavy clay-lands, which before produced little except rye-grafs and coarfe bents, but being fown with red clover, have produced more than fix times the quantity of fodder they formerly did, whereby farmers have been enabled to feed a much greater ftock of cattle than they could do before with the fame extent of ground, which has, at the fame time, enriched the foil, and prepared it for corn; and hence it is now common, where the land is kept in tillage, to lay down their ground with clover, after having had two crops of corn, whereby there is a conftant rotation of wheat, barley, clover, or turnips on the fame land.

And Mr. Donaldfon confiders the general introduction of clover and other cultivated graffes, as one of the greateft improvements in modern hufbandry. The commencement of improvements in the different fpecies of live ftock, in the modes of cultivation, and in the fuperior quality, as well as quantity, of the crops of grain, may all, he thinks, be dated from the period when the fowing of grafs-feeds was firft introduced into the different diftricts of the kingdom.

One acre of red or broad clover will go as far in feeding horfes or black cattle as three or four of natural grafs. And when it is cut occafionally, and given to them frefh, it will probably go ftill much farther, as no part of it is loft by being trodden down.

The red clover is a biennial, perennial plant, whofe roots decay after they have produced feeds; but by eating it down, or mowing it, when it begins to flower, it caufes the

the roots to fend out new fhoots, whereby the plant is continued longer than it would naturally do.

Clover, *Middle*, or *Cow-red* Clover *(Trifolium medium)*, is a plant of the clover kind, which rifes with a branchy ftem, and has a ftrong, deep, ftriking root. It is perennial, flowering in July. Its ftalks are much more branchy and flexuous than in the common clover.

It is a plant that grows naturally in high lands of a chalky quality, and in fuch gravelly foils as have a fubftratum of clay. It is a fort of crop that is fown in thofe improved diftricts, where the land is to continue in a ftate of reft for feveral years, being put in with the white clover. It is found to continue longer in the land, or to be more *abiding* than the common clover, and at the fame time almoft equally productive, efpecially on the poor calcareous defcriptions of land.

Clover, *White*, another plant of the clover kind, *(trifolium repens)* which has a fibrous root and creeping ftem, never rifing nearly fo high as the common or cow-clover. It is perennial, flowering from May to September. It has its name, probably, from its bearing a white flower. It is likewife fometimes denominated *Dutch clover*, from its having been principally imported from Holland. According to Mr. Amos, in the more fertile and moift foils, it becomes more branchy in the ftalks. He confiders it as the fweeteft grafs for all forts of ftock yet known, which makes the clofeft fward, and is very productive of foliage. Hence it is, he thinks, moft peculiarly adapted to laying down land to pafture. It flourifhes moft upon rich, dry, warm foils; but it will accommodate itfelf to moft kinds. It is feldom fown alone, unlefs it be to raife the feed, nor fhould it ever be mown for hay. In laying down rich foils, which are intended to remain in pafture for many years, this feed fhould predominate in the compofition or mixture that is made ufe of for the purpofe.

It grows naturally in moft of the paftures in England, and is generally known among the country people by the name of *white honey-fuckle*. This is an abiding plant, whofe branches trail upon the ground, and fend out roots from every joint, fo that it thickens and makes the clofeft fward of any of the fown graffes; and it is, as has been faid, the fweeteft feed for all forts of cattle yet known; therefore, when land is defigned to be laid down for pafture, with an intention to continue fo, it fhould, as juft obferved, be fown with a pretty full or large proportion of the feeds of this plant. There is an advantage in pafturing white clover, that does not ftrike farmers in general, which is, that each joint of the plant furnifhes a frefh root, and of courfe a frefh plant, whenever fuch joint comes in clofe contact with the foil, and confequently the more it is trodden, the thicker it will get upon the ground. The ufual allowance of this fort of feed is eight pounds to one acre of land; but it fhould never be fown with corn; for, if there is a crop of corn, the grafs will be fo weak under it, as to be fcarce worth ftanding; but fuch is the opinion of farmers in general, that they cannot be prevailed on to alter their old cuftom of laying down their grounds with a crop of corn, though they fhould lofe twice the value of their corn by the poornefs of the grafs, which, in fuch cafes, will never come to a good fward, and one whole feafon is alfo loft; for if this feed be fown in the fpring without corn, there will be a crop of hay to mow by the middle or latter end of July, and a much better after-feed for cattle the following autumn and winter, than grafs which is fown with corn will produce the fecond year. The feed of this fort of clover may alfo be fown in autumn, in the manner directed for the common red clover; and this autumnal fowing, if the feeds grow kindly, will afford a good early crop of hay the following fpring; and if, after the hay is taken off the land, the ground be well rolled, it will caufe the clover to mat clofe under the ground, and become a thick clofe fward.

It has been greatly depended upon by moft cultivators, in bringing lands into a ftate of fward, and is faid to be an extremely ufeful plant on the more rich and dry, fandy and loamy foils, as well as in the clayey and peaty defcriptions of land, where they have been well drained from moifture; but on the more wet and poorer forts of loamy and clayey lands, it is not by any means fo proper or ufeful, as it is not lafting, but gives place to plants of the aquatic kind, as well as others of an indifferent defcription. It is a plant fuppofed by fome not to afford fo fweet an herbage as broad clover, or many others, but in our trials it has, however, always been eagerly fed upon both by fheep and neat cattle; and where clofely fed down, there can be little doubt of its great utility. According to Mr. Goring, as ftated in the communications to the Board of Agriculture, that which comes up naturally by the application of manure is much more hardy than that which is fown, as well as more lafting in the foil. And it has been juftly remarked as a proof of good land, that it runs quickly, of its own accord, to this plant. It may be introduced with moft forts of feeds, and contributes greatly to the fuccefs of the cultivator in the improvement of his grafs lands.

White clover feed is annually imported from Flanders, by way of Holland; but it is not more a native of that country, Mr. Donaldfon fays, than of this, as it is very common in moift paftures, in every county in the kingdom; but the feeds were never collected for fowing in this country till of late years; nor are there many perfons here, even now, who make a practice of faving this feed; though it may be done if the fame method as is practifed for the red clover be taken with this fort; it therefore might be advantageous to farmers who are defirous of improving their land, to fow carefully an acre or two of this white clover for feed, which will fave them the expence of buying for fome years, when the price is high; and there will be a fure market for any quantity they may have to fpare.

By Mr. Young it is ftated as a very profitable article of cultivation, which has of late years been particularly attended to in the counties of Suffolk and Effex, by raifing it alone for feed. The firft growth, contrary to the cafe with red clover, is feeded. Some take a fpring-feeding firft. The returns depend, of courfe, on the price, which varies much, but it has proved a very profitable article, yielding from 7*l.* to 15*l.* an acre. And it is found that wheat fucceeds well after it in moft cafes.

Clover-*Hop*, another plant of the white clover kind *(trifolium procumbens)*, which has a wide-fpreading, flightly branched, procumbent ftem, or ftalk, and a thickifh, fhort, fibrous root. It is a fort of clover that bears a yellow flower, on which account it is called by fome *yellow meadow trefoil.* It grows naturally among the grafs in the upland paftures of this country; but the feeds are frequently fold in the fhops, and are by many mixed with the other forts of clover and grafs-feeds, for laying down ground to pafture. This plant grows with upright, branching ftalks, about a foot high, garnifhed with trifoliate leaves, whofe lobes are oblong and heart-fhaped, but reverfed, the narrow point joining the foot-ftalks. The flowers, which are yellow, grow from the fides of the ftalk, upon long foot-ftalks, collected into oval, imbricated heads, having naked impalements lying over each other like fcales, fomewhat like the flowers of hops, from whence the plant had the name of hop-clover, which grows naturally in this country. There is another variety which is a much ſmaller plant than this, and generally known by the name of none-ſuch, or yellow hop-trefoil. See NONE-*ſuch*.

This ſort of clover is ſtrongly recommended by the following circumſtances: 1ſt. Its not only growing but flouriſhing on the moſt barren ſands, and therefore being a very proper graſs to cultivate on ſuch unfertile ſoils, where any other graſs that is worth notice will ſcarcely grow at all. 2. Its not being apt to ſwell cattle as the red clover does. 3. Its continuing long in good ground, and bearing a very good ſeed, or crop; and, by its flouriſhing both on ſands and clays which have not been ploughed for many years, its being likely to continue long on any ſoil.

In Norfolk, this plant is called *red ſuckling*, and is cultivated about Norwich for the profit of the ſeed, and yields a large quantity, but is ſaid not to have any merit comparable to clover or to trefoil.

CLOVER-*Lay*, or *Ley*, a term which ſignifies the land from which clover has been taken, mown, or paſtured. It is a remark of Mr. Banniſter, that, "where clover-lays have been ſuffered to continue in that ſtate longer than one year, it is a very hazardous experiment to ſow the ground when broken up with wheat or oats, as from the length of time in which the ſurface has been covered with a turf, the worm becomes engendered therein, which often deſtroys the crops of corn; therefore, the ſafeſt way of procedure in the breaking up of theſe old clover-leys, is either to make a fallow of them, or to put them in with peas or other pulſe." From what has been remarked above, it is evident that theſe ſorts of lays require to be managed with conſiderable attention.

CLOVER *Reaping machine*, is an implement conſtructed for the purpoſe of reaping and collecting the heads of ſuch clover-crops as have been let remain for ſeed. Various contrivances of this ſort have been ſuggeſted by writers on huſbandry, but there is probably none that anſwers the purpoſe in a perfect manner.

It has been ſuggeſted by Mr. Marſhall, in the "Rural Economy of the Southern Counties," that, "as the great difficulty in the ſecuring of the clover for the purpoſe of ſeed, is that of getting the herbage ſufficiently dry, in the dewy and damp ſeaſon at which the ſeed becomes ripe, that light bags, formed of thin cloth or fine wire, might be uſeful for collecting, catching, and retaining the heads, which moſtly riſe above the herbage, by being fixed upon the handles of the ſcythes as they are ſwept off by them, being emptied as there may be neceſſity, as, in this way, the herbage by being left upon the ground, would be of three times the value of the muſty ſtraw afforded by ſeed-clover, either for the purpoſe of being eaten off, or turned down as a manure. Beſides, the heads, by being well dried in wet weather in the houſe, and in dry ſeaſons in the open air, the ſeed would, it is ſuppoſed, not only be preſerved with more certainty, but in a much better ſtate in reſpect to the ſample, and of courſe, in moſt ſeaſons, be of much greater value."

CLOVER *Threſhing-machine*, in *Rural Economy*, an implement contrived for the purpoſe of cutting off and collecting the heads of ſuch crops of clover as have been let remain in order to afford ſeed.

Various machines of this ſort have been invented at different times, but probably without being perfectly adapted to the buſineſs. Long ago an account was given, in "Bradley's Syſtem of Huſbandry and Gardening," of a machine employed for this purpoſe in Flanders, where this ſort of crop was introduced and cultivated at a much earlier period than in this country, and which he has deſcribed in the following manner. "He has ſeen," he ſays, "two or three ways of threſhing out clover-ſeeds by engines in that country, after the heads of the ſeeds are thraſhed off by common flails. The engine which he beſt remembers has a hopper at the upper end of a trough, ſo that the heads of the ſeed fall conſtantly from the hopper into the trough. The trough is about ſix feet long, and about two feet and a half over, and lies ſlopewiſe from the hopper, which is at the higher end, ſo as to drop at the other end about a foot. The bottom of this trough within-ſide is made rough by chiſſels, and upon it is a board made to draw backwards and forwards, which is cut in a rough manner like the inſide of the bottom of the trough. When the ſeeds fall into the trough at the upper end, the broad board, in its motion, draws them through the trough, and thereby breaks or opens the ſeed-veſſels, ſo that the chaff and the ſeeds run out of the lower end ready for winnowing. This motion is maintained by a water-wheel and crank, and anſwers the purpoſe it is deſigned for very well. He has alſo ſeen an engine of this kind where the bottom of the trough was a hurdle, more finely wrought than the common hurdles; and the ſliding part, which he calls the broad board, was a hurdle of the ſame make. In this he found, that moſt of the pure ſeed fell through the lower hurdle, and little more than chaff was diſcharged by the lower end of the trough, and conſequently muſt give leſs trouble in the winnowing or cleaning from the chaff. He has alſo ſeen another kind of mill, or engine, for this purpoſe, which ſomewhat reſembles the mills which tanners uſe in grinding bark. In the former, he ſhould have mentioned, that there is commonly a weight laid upon the upper hurdle, or board, the better to break the heads of ſeed that paſs between that and the bottom of the trough. And from the great ſimplicity of this machine, the author of the "Preſent State of Huſbandry in Great Britain" thinks it is ſurpriſing that ſome ſuch has not been long ſince erected for the purpoſe in England, where ſuch great quantities of clover-ſeeds are annually ſaved. Were threſhing-mills generally erected in this kingdom, it is highly probable," he ſays, "they might in time be made not only to thraſh off the heads of the clover from the ſtalks, but, by means of ſome ſuch machinery as above deſcribed, be made alſo to ſeparate the ſeeds from the huſks of the clover crops.

CLOUET, PIETER, in *Biography*, an engraver of ſome repute, native of Antwerp, who, after he had learned the firſt principles of his art, went to Rome, where he reſided many years, ſtudying under Spierre and Bloemart: having completed his ſtudies he went to Paris, where he lived ſome time, and from thence retired to the place of his birth, and there died aged 62 years. His prints, though ſomewhat deficient in harmony and effect of Chiaro-ſcuro, occaſioned by the too equal diſtribution of the lights and ſhadows, are engraved in a firm and bold manner, ſomething reſembling that of Pontius. He engraved many prints from Rubens, which are much eſteemed. Amongſt the beſt may be reckoned the Death of St. Anthony, a large upright plate; the Deſcent from the Croſs, the ſame; a Converſation, where ſeveral lovers are repreſented in a garden, a large plate length-ways, and a landſcape with a cottage, where the ſnow is repreſented falling; this, which is a large plate length-ways, makes one of a ſet of ſix: the other five were engraved by S. Bolſwert. Strutt. Heinecken.

CLOUET, ALBERT, nephew of the preceding artiſt, was born at Antwerp, and like his uncle, went to Italy to perfect himſelf in his art. He ſtudied ſome time under Cornelius Bloemart at Rome, and engraved ſeveral of the prints from the gallery of *Pietro* da Cortona, in the palace Pitti at Florence, with a near reſemblance to the ſtyle of his maſter. Beſides a great number of other portraits, he engraved

engraved thofe introduced in the lives of the painters by Bellori. The dates on his prints, cited by Heinecken, are from 1641 to 1675. Strutt. Heinecken.

CLOUGH, or *Draught*, in *Commerce*, an allowance of two pounds in every hundred weight for the turn of the fcale; that the commodity may hold out weight when fold out by retail.

Clough, or *Clogh*, in *Geography*, a fmall poft-town of the county of Down, Ireland, which has a fair for mountain fheep. There is a caftle built in a Danifh fort, which is very unufual, and which, from being too fmall for the refidence of a refpectable family, muft have been built merely for defence, for which its fituation is excellent. It is 69 miles N. from Dublin. Survey of Down.

There are other villages called *Clogh*, and fome places to which this word is a prefix, its fignification in the Irifh language being *a ftone*.

Clough, or *Clyfe*, is the fame with paddle, fhuttle, &c. being a kind of fluice or pen-ftock; ufed for retaining or letting go the waters of canals, ponds, mill-dams, &c.

Clough-*arches*, or *Paddle-holes*, in the conftruction of *canals*, denote the crooked arches, which convey the water from the upper pound into the chamber of the lock, when it is to be filled, and when the cloughs or paddles are drawn up. See *Plate* V. *Canals*, *fig*. 36 and 37.

CLOVIO, Don Giulio, in *Biography*, fo juftly celebrated for his aftonifhing miniatures and illuminations in miffals and other religious books, was born in Sclavonia in the year 1498. He was originally educated for the church, and took orders, but was afterwards fuffered to relinquifh the facerdotal habit by a difpenfation from the pope. Soon after the age of eighteen, his love of painting prompted him to travel to Rome, where he was taken into the fervice of the cardinal Grimani, by whom he was, for the fpace of three years, employed in making careful pen-drawings from the fineft medals.

He afterwards became the fcholar of Giulio Romano, and made confiderable advancement in oil-painting; but his mafter, perceiving the extraordinary talent which he evinced for miniature, fucceeded in perfuading him to apply himfelf entirely to that branch of the art; and it may with juftice be faid, that we owe to the fagacity of Giulio Romano, and the unexampled affiduity of Clovio, the moft exquifite and delicately finifhed performances of that kind in the known world; fince he not only far furpaffed all who went before him, but to this day ftands unrivalled, by all thofe who have fince attempted to walk in his footfteps. In addition to the inftruction which our artift received from the favourite fcholar of Raffaele, he derived great benefit from the works of Buonaroti, many of which he copied in a moft beautiful and finifhed manner; and he afterwards reaped great advantage from the friendfhip and experience of Girolamo da' Libri, a miniature painter of great note at Verona: the refult of all thefe ftudies was a ftyle of drawing, partaking of the purity of the Roman, and the grandeur of the Florentine fchool; united, not unfrequently, to the rich colouring of Titian or the ambient hue of Coreggio.

Amongft the furprizing labours of Don Giulio Clovio, defcribed by Vafari, that writer particularly dwells upon an *ufficio della madonna*, painted for the Cardinal Farnefe. In this work many portraits were introduced, and the figures, though in fome cafes no longer than fo many ants, were reprefented with as much diftinctnefs in all their parts, as if they had been drawn the fize of life.

A beautiful miffal, illuminated by Clovio, formerly belonging to Alexander Champernoun, efq. is now in the poffeffion of the Townley family. Several prints from the works of this mafter, are cited by Heinecken. He died aged 80, in the year 1578. Vafari. Lanzi, Storia Pittorica.

CLOVIS I., the firft Chriftian king of France, fucceeded his father Childeric I. in the year 481, when he was but 14 years of age. He was not long in freeing his country from a formidable domination, and in putting an end to the empire of the Romans in Gaul. In 486 he defeated Syagrius, the Roman general, at Soiffons, which he afterwards made the feat of his royalty. Syagrius fled to Thouloufe, claiming the protection of Alaric, king of the Vifigoths, by whom, however, he was finally given up to Clovis. The king, for fome time, amufed him with promifes of enlargement, and thereby obtained new conquefts; but at length caufed him to be beheaded privately. The power of the Romans being thus deftroyed, the French found themfelves mafters of all the provinces fituated between the Rhine and the Loire. At this period the rights of kings were of a very limited nature, which ill accorded with the haughty fpirit of Clovis; he felt that it was neceffary to fubvert the powers of the foldiers, in order to eftablifh and augment his own. An opportunity for this purpofe foon prefented itfelf. A rich vafe was taken from a church at Rheims, which the bifhop anxioufly defired might be reftored. Clovis was inclined to grant his wifhes, and at the divifion of the fpoil claimed the vafe as his own. "Hold," exclaimed a foldier, with his battle-axe raifed, "thou fhalt have no other than the fhare which may fall to thy lot." Clovis, at the time, diffembled his anger, but he fhortly after took occafion to charge the man with fome trifling offence, and telling him to recollect the vafe, ftruck off his head with a fingle blow. This act of authority, dictated only by the mean and favage fpirit of revenge, impreffed his army with reverence for his authority, and eftablifhed a fort of boundary between the rights of kings and thofe of the people. In 493, Clovis married Clotilda, daughter of Childeric, formerly king of Burgundy. She was a zealous Chriftian, and took every means in her power to convert the king. For three years fhe ftrove in vain, when, feeing himfelf in danger of a defeat, he invoked the God of the Chriftians, vowing an adherence to him, if by his affiftance he might be enabled to conquer his enemies. He rallied his troops, gained a complete victory, and was, with 3,000 of his fubjects, immediately baptized by the bifhop, for whom he had formerly endeavoured to fave the vafe. France became now a Chriftian country, and this revolution, from paganifm to Chriftianity, feems to have been effected with no more difficulty or difturbance, than any common regulations of the ftate. "Indeed," fays a good writer, "when a fierce and barbarous people received the Chriftianity of that age, they rather made its genius bend to their difpofition, than formed themfelves upon its precepts; and a compliance with fuperftitious rights and ceremonies, with fubmiffion to ecclefiaftical authority, and profufe liberality to religious foundations, conftituted the whole of their new obligations." The true genius and fpirit of the Chriftian religion were little underftood in that day. Clovis himfelf, when affected by a detail of Chrift's fufferings, exclaimed "Oh that I had been there I would have revenged his injuries." The king foon attained the high honour of being reckoned the only catholic king in Europe, all the other princes being Arians, and the emperor Anaftafius was regarded as not perfectly orthodox. Clovis meditated the moft extenfive plans, and was defirous of uniting under his domination all the territory which extends from Langres to Geneva, and from the Pyrenées to the banks of the Loire. He waged

 a fuca fuccefsful war againft his wife's uncle, Gondebaud, from whom he exacted a heavy tribute, on pretence that Alaric, whofe dominions he had long coveted, was guilty of herefy; he fell a victim to the ambition of Clovis. His career was, however, checked by his brother-in-law, Theodoric, king of the Oftrogoths, who defeated him at Arles. Clovis, rendered defperate by this mifcarriage, fell on, and deftroyed all that he encountered in his retreat. To facilitate his ambitious projects, he prevailed on Clodoric to affaffinate his own father, Sigebert, and then had the parricide put to death, that he might have fewer obftacles, with which to contend in invading his territories. Having taken by furprize a chief of one of the little ftates, by which his own dominions were furrounded, he caufed his head to be fhaved, becaufe he had the title of king, which he wifhed to belong exclufively to himfelf. Such was the ancient mode of declaring a prince incapable of wearing a crown. The fon of the infulted chief obferved to his dejected parent, "that the branches would one day fhoot out again, fince the trunk had not been divided." Clovis enraged at the fpeech ordered both father and fon to be beheaded. Having extended his conquefts from the mouth of the Rhine to Thouloufe, Clovis took up his refidence in Paris, which he made the feat of his empire, and which remained for fourteen centuries the metropolis of the French monarchy. He then adopted the policy of overthrowing the little independent ftates and royalties of Gaul, and bringing them all under his own authority, and in purfuing this plan he fcrupled not to employ treachery and affaffination. To expiate his crimes he founded feveral monafteries, and built a great number of churches, at the inftigation of his clergy, who perfuaded him that, by fuch acts of royal munificence, he would fecure the pardon of his fins. Clovis died in 511, at the age of forty-five years, in the thirtieth year of his reign, and was buried in the church of St. Peter and St. Paul, which is now called St. Genevieve. He left four fons, for each of whom he had prepared a kingdom. Clovis was author of the Salic law, which excludes the wife from any fhare of inheritance. It likewife gave rife to the exclufion of females from the fucceffion to the throne of France. See SALIC *Law*. Hift. Univer. Du Frefnoy.

CLOVIS II. king of France, fucceeded his father, Dagobert, in the kingdoms of Neuftria and Burgundy in 638, while he was a very young child. He is mentioned in this work on account of fome traits of humanity which are attributed to him; of thefe the moft remarkable was, that of ftripping the gold and filver plates which ornamented the coffins of St. Denis and his companions, in order to purchafe corn for the poor in a time of fcarcity. This action has been reprefented by fome monkifh writers as the caufe of an infanity, with which, it is faid, he was afflicted, and to which they impute the ftupidity of his defcendants. Clovis married a beautiful young girl, who had been purchafed of fome Englifh merchants by the mayor of the palace, and prefented to the fovereign; by her he had three fons, none of whom emerged from obfcurity. Of Clovis III. nothing is recorded meriting our notice.

CLOUS *d'Artillerie et de Travaux militaires*, nails for artillery and military works. Thefe are of different kinds, lengths, thickneffes, forms, and denominations, and are particularly defcribed in this work, under the feveral names or appellations they bear.

CLOUT, in *Agriculture*, is an iron plate put on the end of the axle-tree of a cart, or other carriage, to prevent its wearing.

CLOUT-*Nails*. See NAIL.

CLOUTED CREAM, in *Rural Economy*, fuch cream as is raifed by means of the milk being heated.

CLOUTS, in *Gunnery*, are thin plates of iron nailed on that part of the axle-tree of a gun-carriage, which comes through the nave, and through which the linfpin goes. See [illegible]

CLOWADOK, in *Geography*, a river of South Wales, which runs into the Ython, at Llanbadern in Radnorfhire.

CLOWES, WILLIAM, in *Biography*, an eminent furgeon of the fifteenth century, received his education under George Keble, whofe fkill in the art he ftrongly commends. He was for fome time furgeon in the navy, as he fays he was on board her majefty's fhip the Aide, in the year 1570, when the emperor's daughter married the king of Spain. He fome time afterwards fettled in London, and was made furgeon to Chrift's and Bartholomew's hofpitals. He appears to have been in high eftimation, and to have had a confiderable fhare of practice, as he fpeaks of cures performed by him on perfons at Town-Malling, in Kent, and other towns and villages in the vicinity of London. In 1586 he was ordered to go to the Low-Countries, to the affiftance of the army under the earl of Leicefter. On his return he was appointed furgeon to the queen. From various paffages in his publications, we find that a ftrict friendfhip fubfifted between him and Banifter, who was no lefs famous for his profeffional abilities. We learn alfo, from the fame fource, that he had ferved under the earl of Warwick, and had been a retainer to lord Abergavenny. At what time he died is not known. The lateft date in his works is in 1596, at which time he appears to have been in full practice. As an author he is deferving of confiderable credit. His works are in Englifh, and he ftrongly defends the practice of writing in our vernacular language; at the fame time, from his frequent quotations from Galen and Celfus, he fhews he had a competent fhare of learning. His firft publication is entitled, "A Brief and Neceffary Treatife touching the Cure of the Difeafe, now ufually called Lues Venerea," printed in 1585, reprinted in 1596, and again in 1637. He fpeaks of the increafed frequency of the difeafe, and fays, that in the fpace of five years he had cured more than a thoufand patients infected with it, at Bartholomew's hofpital. He ufed mercurial frictions, and occafionally turbith mineral, mercurius diaphoreticus, which he highly commends. He alfo gives formulæ for purging potions, diet drinks, fumigations, ointments, plaifters, cauftics, &c. His next publication, which appeared firft in 1588, and which has obtained for him the greateft credit, was an approved practice for all young chirurgeons, concerning burnings with gun-powder, and wounds made with gun-fhot, fword, halberd, pike, lance, &c. the refult of much practice and obfervation, while employed as an army furgeon, ftrengthened by obfervations from the moft approved writers, and containing all that was then known on the fubjects treated of. In the treatment of gun-fhot wounds, and of punctures of the nerves, he profeffes to ufe emollient and foothing applications, though they would hardly be efteemed fo at this time; they were, however, an improvement on what he had been accuftomed to fee in the early part of his practice. He relates the cafe of a perfon whofe fkull was fractured, in which he ufed the trepan fuccefsfully, and of a compound fracture of the leg, which he cured without amputating the limb. In fhort he may be juftly ranked among the reftorers and improvers of furgery. To the fecond edition of this work, publifhed in 1591, he added a tranflation of a treatife on the venereal difeafe, by John Alucenar, a Spanifh phyfician, and fome aphorifms relative to furgery, in Englifh and Latin. The firft of the pieces was delivered to him, he fays, by a friend; the latter he found among fome old books of furgery. Clowes was a rational practitioner, and appears to have

have had an enlarged, intelligent, mind. He every where laughs at quacks and impoftors, particularly at thofe juglers who pretended to charm away difeafes, and tells a merry ftory of one old beldam, who was put on her trial for ufing witchcraft in the cure of difeafes. The judges, who faw the ignorance, as well as the malice of the profecutors, told the dame, if fhe would divulge her charm fhe fhould be fet at liberty. This fhe readily did, to the no fmall diverfion of the court, when fhe informed them, that it confifted in repeating the following words, after receiving the ftipulated pay, a loaf of bread and a penny:

My loaf in my lap,
My penny in my purfe,
Thou art never the better,
And I am never the worfe.

But we have little reafon to laugh at the credulity of our anceftors, while we fuffer ourfelves to be impofed upon by ftories of the efficacy of tractors, and other equally infignificant and contemptible pieces of juglery and impofture. Aikin's Biograph. Memoirs.

CLOWEY, in *Geography*, a lake of North America, N. lat. 62° 20'. W. long. 106° 15'.

CLOWNS' ALL-HEAL, in *Botany*. See STACHYS *Sylvatica*.

CLOWNS' *Wound root*. See STACHYS.

CLOYE, in *Geography*, a town of France, in the department of the Eure and Loire, and principal place of a canton in the diftrict of Chateaudun; the place contains 1520, and the canton 10,751 inhabitants; and the territory includes 245 kilometres, and 15 communes.

CLOYED. The feamen, when any thing is got into the touch-hole of a great gun, fo that they cannot with a priming-iron make way for the powder to be put in to prime it, fay, *the touch hole is cloyed*; wherefore, when guns are nailed, &c. they fay they are *cloyed*.

CLOYNE, in *Geography*, a fmall town of the county of Cork, Ireland, remarkable only for being the fee of a bifhop. The cathedral is a fine old building, and within a fhort diftance of it there is a well preferved round tower. The bifhopric lies entirely within the county of Cork, extending eaft and weft near 50 Irifh miles in length, by a breadth of 23. It contains 137 parifhes, which have been reduced to 69 benefices; though they contain 539,700 Irifh acres. The patronage of the bifhop is confiderable; and the wardenfhip of the church of Youghel, and a union of parifhes near Cloyne being united to the bifhopric, this fee is ufually reckoned amongft the beft. The celebrated Berkley was one of its bifhops. Cloyne is within a fhort diftance of the fea, about 14 miles eaft from Cork.

CLUACA, in *Ancient Geography*, a town of Afia, in Media, according to Ptolemy.

CLUACARIA, or CLUCAR, a town of Africa.

CLUACINA, in *Mythology*, an epithet of Venus, derived, as fome fay, from *Cluo*, to hear, liften, or agree; or, according to others, fignifying to fight. Her image was erected in the place where peace was concluded between the Romans and Sabines.

CLUALE, in *Geography*, a town of America, in Georgia; 15 miles S. of Oakfufkee.

CLUANA, a maritime town of Italy, in the Picenum, fituated at the mouth of a river. Pliny.

CLUB *a battalion, to*, a low, vulgar, military phrafe, implying both the confufion which a body of men gets into by falfe directions given to its different component parts and a temporary inability, on the part of the commanding officer, to reftore them to their natural front in line or column. Officers, who are inexperienced, and but indifferent tacticians in the fubordinate parts, may frequently commit this error. The confufion, however, fometimes happens through an erroneous movement of a divifion or company, even when the word of command has been correctly given. An officer fhould know how to unravel the feveral parts immediately. But if he is puzzled, he fhould caufe the *difperfe* to be founded for the troops to repair in loofe and defultory order to fome rallying point, and there to re-affemble in their natural line of formation. A general, however, may be a perfect judge of pofitions, and underftand thoroughly the principles of attack and defence without having minutely ftudied or particularly attended to the drill and the mere mechanical arrangements of inferior movements; whereas one, whofe attention is chiefly directed to fuch objects, is feldom or ever fit to be entrufted with the command of an army on actual fervice, or in the field, where but few of the manœuvres ufually taught and attended to are either ufeful or can be advantageoufly put in practice. And it ought always to be remembered by thofe, who write or fpeak on the attack and defence of this country, though none of them feem to have fo much as once adverted to the fact, that neither the Pruffian nor German tactics can be made ufe of with advantage in either attacking or defending it. At the fame time it muft be acknowledged, that a general fhould attend to the minutiæ as well as to the fublimer parts of his profeffion, allowing, however, to each their juft and proportionate claim to his attention.

CLUB *antennæ*, in *Natural Hiftory*, a name given by naturalifts to fuch of the horns or antennæ of butterflies as reprefent a *club*, being larger at the extremities than at the origin.

CLUB-*foot*, or *club-footed*, a diftortion fo called. See FOOT, *Diftortion of the*.

CLUB-*haul*, in *Sea-Language*, denotes a method of tacking a fhip, when it is expected fhe will mifs-ftays upon a lee-fhore.

CLUB-*Mofs*, in *Botany*. See LYCOPODIUM.

CLUB-*Rufh*. See SCIRPUS.

CLUDRUS, or CLUDROS, in *Ancient Geography*, a river of Afia Minor, in Caria, according to Pliny, who fays that the town of Eumenia was fituated on its banks.

CLUE *of a Sail* See CLEW.

CLUGNY, in *Geography*, an ifland in the Southern Indian Ocean, difcovered by Kerguelen, near Kerguelen's land.

CLUIS DESSOUS, a town of France, in the department of the Indre, two leagues N.W. of Aigurande.

CLUIS *Deffus*, a town of France, in the department of the Indre, and diftrict of Chateauroux, 10 miles E. of Argenton.

CLUMP, in *Ornamental Gardening*, a detached portion of ground, dug up on lawns, or other parts of pleafure-grounds, fo as to be confiderably raifed in the middle for the purpofe of receiving different forts of trees, fhrubs, flower and other plants of the ornamental kind, in order to fhow them more fully, and produce a better effect. They differ from borders in being perfectly detached and feparate, as well as in being much more raifed in the operation of digging them over. This fort of ornamental compartment is not, however, at prefent fo much in ufe as formerly, except in very fmall defigns. But in extenfive grounds, where there is much mown grafs or lawn, when occafionally introduced, they have a good effect. It has been obferved by the author of "Ornamental Planting," that "detached maffes of wood, as well as groups and fingle trees, give a kind of animation to a fcene;

a ſcene; and this may be a reaſon why Brown was ſo laviſh of them: but that a crowd of clumps, as a profuſion of ſingle trees, muſt ever disfigure the ſcene they appear in."

In the forming of compartments of this nature, great care ſhould be taken to have them properly proportioned to the nature of the ſituation and extent of ground, as nothing can be more offenſive or diſguſting than clumps diſproportionately large. The diſtribution of them in the ground ſhould likewiſe be well attended to, in order that they may produce the moſt certain and ſtriking variety and effect: this is much aſſiſted by their being duly but irregularly intermixed with the other ornaments of the ſcite on which they are introduced.

In the buſineſs of planting them, the trees and large growing ſhrubs ſhould be conſtantly placed towards the back parts or middles, while the ſmaller ſhrubs and flower plants occupy the fore parts, being all properly intermixed according to their habits and methods, as well as times of flowering; as, by a judicious management in this reſpect, they produce a much better variety and effect, and continue much longer in beauty.

All the finer ſorts of flowering trees, ſhrubs, and other plants, are here proper, as well as a ſlight mixture of thoſe of the more common kinds.

The annual management of clumps is merely that of digging them over once or twice, trimming, and removing all the old ſtems and decayed parts of the plants and ſhrubs, raking them over neatly in the early ſpring ſeaſon, and putting in ſuch annual ſeeds as may be thought proper. See Bosquet.

Clumps, in *Agriculture*, are portions of land planted with different ſorts of trees in a cloſe manner, for the purpoſe of affording ſhelter and protection to the ground or live ſtock kept upon it.

CLUN, in *Geography*, a river of England, which runs into the Temde, 5 miles W. from Ludlow, in Shropſhire.

CLUNCH. By this name miners and well-diggers, &c. denominate a variety of ſtoney matters which they meet with in digging. In the clay which is met with below the ſand ſtratum, which crops in Leighton, Woburn, Ampthill, Sandy, and other pariſhes in Bedfordſhire, two remarkable layers of whitiſh ſtone called clunch are met with, near the part of the clay abounding with large perforated gryphites: theſe clunches are not much harder than chalk, and contain within them very beautiful and large ſpecimens of cornua ammonis, of ſmall bivalve ſhells called anomia or pundibs, and ſmall pieces of rotten wood, in a ſoft or almoſt pulpy ſtate: what is remarkable, and may tend to throw ſome light upon the bitumenization of wood in the ſtrata, is, that ſome ſpecimens of this ſoft wood taken out of the clunch being immerſed in a phial of water, were, after ſome months, ſhrunk very greatly, particularly in thickneſs, and were found hard, and their fracture to be ſmooth and ſhining like the bitumenized wood which is found in other ſtrata, particularly in the purbeck potters, or white pipe-clay ſtratum.

CLUNDERT, or Klundert, a ſtrong town of Holland, formerly called "Neuwervaert," ſeated on a river or canal, which runs from the Merwe, and forms the tract on which this town and Williamſtadt ſtand into an iſland. It was taken by the French in March 1793, and ſoon after evacuated; 10 miles W.N.W. of Breda. N. lat. 51° 39'. E. long. 4° 28'.

CLUNG, in *Rural Economy*, ſignifies cloſed up, or ſtopped; ſpoken of hens, when they do not lay. It is alſo applied to wood or any other thing that is ſhrivelled or ſhrunk up, when it is ſaid to be clung. Aſh-timber is ſometimes ſo much clung, that it cannot be ſplit into hoops or other ſimilar forms. And in this ſtate it is improper for the uſe of coopers.

CLUNIA, in *Ancient Geography*, a town of Hither Spain, S.W. of Numantia, which became a Roman colony and "conventus." Suetonius in his Life of Galba (c. 8.) informs us, that this prince governed Hiſpania Tarragonenſis for eight years, and that during this period Vindex revolted againſt Nero, and invited Galba to unite with him in reſcuing the empire from tyranny. It was in this town that a prieſt of Jupiter, admoniſhed in a dream, found in the ſanctuary of a temple a prediction, delivered 200 years before, which announced that a man ſprung from Spain would poſſeſs the empire of the world. This prediction, and the revolt of Vindex, determined Galba to ſeize the empire, under the modeſt title of lieutenant of the ſenate and of the Roman people. It was, moreover, at Clunia, that Galba, after receiving intelligence of the defeat and death of Vindex, received information, that the ſoldiers, ſenate, and Roman people had given him the title of emperor. This prince, in acknowledgment of theſe favourable occurrences, celebrated Clunia on his medals, by the name of Sulpicia, under which appellation it was honoured by Galba. On one medal the emperor is repreſented ſeated and receiving the victory preſented by the goddeſs of the city. This place is now denominated *Corunna* or *Corunna del Conde*.

CLUNIUM, a town of the eaſtern part of the iſland of Corſica, according to Ptolemy

CLUNY, or Clugni, in *Geography*, a town of France, in the department of the Saône and Loire, and chief place of a canton in the diſtrict of Mâcon, ſituated between two mountains on the Rhone. The church is ſuppoſed to be one of the largeſt in France, and the town includes three pariſhes. The place contains 3814, and the canton 15,567 inhabitants: the territory comprehends 262½ kiliometres and 23 communes; 3½ leagues N.W. of Mâcon, and ſeven S. of Châlons-ſur-Saône. In this place was a celebrated abbey of Benedictine monks, being the head or chief of a congregation denominated from them. It was founded by William, duke of Berry and Aquitain; or, as others ſay, by the abbot Berno, ſupported by that duke, in the year 910; but owed its diſtinguiſhed reputation to Odo, who, upon the death of Berno, was created abbot of Clugni in 927. This zealous eccleſiaſtic not only obliged the monks to live in a rigorous obſervance of their rules, but alſo added to their diſcipline a new ſet of rites and ceremonies, which, notwithſtanding the air of ſanctity that attended them, were in reality inſignificant and trifling, and yet at the ſame time ſevere and burthenſome. This new rule of diſcipline was productive of glory to its author, and, in a ſhort time, was adopted in all the European convents; for moſt of the ancient monaſteries, which had been founded in France, Germany, Italy, Britain, and Spain, received the rule of the monks of Clugni, to which alſo the convents, newly eſtabliſhed, were ſubjected by their founders. Thus it was, that the order of Clugni attained to that high degree of eminence and authority, opulence, and dignity, which it exhibited to the Chriſtian world, in the following century. Moſheim obſerves, (E. H. vol. ii. p. 413,) that the "order of Clugni," was not, as ſome have repreſented it, a new ſet of monks, ſuch as were the Carthuſian, Dominican, and Franciſcan orders; but ſignified only, *firſt*, that new inſtitution, or rule of diſcipline, which Odo had preſcribed to the Benedictine monks, who were ſettled at Clugni, and, afterwards, that prodigious multitude of monaſteries throughout Europe, which received the rule eſtabliſhed at Clugni, and were formed by aſſociation into a ſort of community, of which the abbot of

Clugni

Clugni was the chief. Towards the close of the 12th century a jealousy arose between the Cistercians and the monks of Clugni, which, after several dissentions, produced at length an open rupture, and declared war between these two ancient and powerful monasteries. The monks of Clugni accused the Cistercians of affecting an extravagant austerity in their manners and discipline; while the Cistercians, on the other hand, charged them, and on very just grounds, with having degenerated from their former sanctity and regularity of conduct. St. Bernard, the oracle and protector of the Cistercians, wrote, in the year 1127, an apology for his own conduct in relation to the division that subsisted between the two convents, and inveighed with a just, though decent, severity against the vices that had corrupted the monks of Clugni. He accuses them of luxury and intemperance at their table, of superfluity and magnificence in their dress, their bed-chambers, their furniture, equipage, and buildings. He points out the pride and vanity of the abbots, who appeared more like the governors of provinces than the spiritual fathers of humble and holy communities, whose original profession it was to be crucified and dead to the interests and pleasures, the pomps and vanities, of the present world. He declares, with a pious concern, that he knew several abbots, each of whom had more than 60 horses in his stable, and such a prodigious variety of wines in his cellar, that it was scarcely possible to taste the half of them at a single entertainment. This charge was answered with uncommon moderation and candour, by Peter Mauricius, abbot of Clugni; and hence it occasioned a controversy in form, which spread from day to day its baneful influence, and excited disturbances in several parts of Europe. It was, however, followed with a much more vehement and bitter contest concerning an exemption from the payment of tythes, granted among other privileges and immunities to the Cistercians, A. D. 1132, by Innocent II. This keen dispute was, in some measure, terminated in the year 1155. Mosheim, E. H. vol. iii. p. 67.

This order of monks was brought into England by William, earl of Warren, son-in-law to William the Conqueror, who built a house for them at Lewes in Sussex, about the year 1077. There were twenty-seven priories and cells of this order in England, which were governed by foreigners, afterwards made denizens.

CLUPEA, in *Ancient Geography*. See CLYPEA.

CLUPEA, in *Ichthyology*, a genus of abdominal fishes. The character of the genus consists in the head being compressed; mouth compressed and rough within; jaws unequal, the upper with serrated mystaces; tongue short, rough, with inverted teeth; eyes moderate, round, and marginal; gills setaceous; the gill-covers of either three or four plates; and the gill-membrane eight-rayed; body compressed, elongated, and covered with scales of moderate size; lateral line straight, near the back, and running in a parallel direction to it; belly carinated and generally serrated; ventral fins usually nine-rayed; tail forked.

Species.

THRISSA. Anal fin with twenty-eight rays; last ray of the dorsal fin long and setaceous.

This fish is about twelve or fourteen inches in length; the back bluish-green, with rows of brownish spots; the sides of the head green, and of the body silvery white. It inhabits the shores of America and India, and is considered poisonous.

SETICORNIS. Lateral bones of the upper jaw setaceous; anal fin with thirty two rays. A native of the Pacific Ocean. The body is of a lanceolate form, with the back bluish, and the belly silvery; the scales smooth, deciduous, somewhat of a rhombic form and obliquely imbricated.

CYPRINOIDES. Belly obtuse. Length less than twelve inches. The body is of an oblong form and silvery colour, with the back bluish, and the scales disposed in ten longitudinal series. A tropical fish. *Camaripugaucu* of Ray.

TROPICA. Tail cuneated, or wedge-formed.

Inhabits the coasts of Ascension island; the body is white, compressed, broad, and serrated.

SINENSIS. Outer ray of the gill-membrane truncated behind. A species which inhabits the coast of China; in its general figure, this fish is broader than the common herring, but in other respects resembles it.

MYSTUS. Body ensiform; anal fin joined to the tail. Linn. A native of the Indian seas.

ATHERINOIDES. Lateral line silvery. Gmel. This kind inhabits Surinam. The lower jaw is shorter than the other.

HAUMELA. Body lanceolate, naked, and destitute of ventral, anal, or caudal fins: dorsal fin extending the whole length of the back; tail linear.

This and the following species are described by Forskal as natives of the red sea; they seem both very doubtful.

DORAB. Ventral fins minute; upper lip two-horned, with extended teeth; lower longer, the teeth strong and erect.

VILLOSA. Lateral line prominent and rough. Müller. A native of the north sea,

TUBERCULATA. Lower jaw longer: on the snout a wart-like protuberance, and a red spot at the upper commissures of the jaws. La Cepede.

A small species observed by Commerson, in the Indian seas, and said to be an excellent fish for the table.

FASCIATA. Above, marked with semi-current dusky bands; below, with rounded spots. La Cepede. Inhabits the Indian seas, and was found by Commerson.

MACROCEPHALA. Above bluish, with the head elongated; upper jaw longest: fins red. La Cepede.

Described from a drawing, made by father Plumier, of a fish taken in the American seas.

ALOSA. Sides marked with a longitudinal series of spots; snout bifid.

This is the common shad, a fish which inhabits the Mediterranean and northern seas: it is of the marine kind, but at particular seasons ascends rivers for the purpose of depositing its spawn, and which it is observed to lay in the deepest part of the river. Towards autumn this fish returns again to the sea. Usual length from eighteen inches to two feet.

The young of this species has been very recently ascertained by us to be no other than the little fish known commonly by the name of white bait. The history of that heretofore ambiguous fish has excited the curiosity of so many naturalists, that we cannot refrain repeating, in this place, a few observations that have lately fallen from us on the same subject, in the "Natural History of British Fishes."—We have there observed that when the true character of the white bait becomes more generally understood, and the veracity of those remarks we shall offer in the sequel is sufficiently confirmed, by the observations of other naturalists, it will perhaps appear that it has remained with us to remove the mysterious veil that has hitherto enveloped the history of this little fish in obscurity. To what peculiar circumstances we are to attribute the errors that have prevailed among writers, respecting this fish, we cannot easily imagine: unless, as we must suspect, they never had an opportunity of examining it; but that they have actually been deceived, we are perfectly satisfied. This assertion is not advanced on slight surmises, for some pains have been taken by us to investigate the history of this heretofore ambiguous fish: we have examined

examined it repeatedly, and have now before us a variety of ſpecimens, elucidatory of the different tranſitions of its growth, from a diminutive ſize to the full length of three or four inches. Every one of theſe bears the moſt ſtriking ſemblance of the parent fiſh, and affords an incontrovertible evidence, that the white bait is really the fry of the common ſhad. We ſhall premiſe our enquiry by introducing the obſervations of Mr. Pennant concerning it, in the reſult of which he labours to prove, that the white bait is not the young ſhad, or even fiſh of the clupea, but one of the cyprinus genus, approaching near to the bleak, and ſhall conclude with ſtating our reaſons for diſſenting from an opinion ſo long eſtabliſhed, and ſo uniformly adopted by later writers.

"During the month of July (ſays Mr. Pennant) there appear in the river Thames, near Blackwall and Greenwich, innumerable multitudes of ſmall fiſh, which are known to the Londoners by the name of *white bait.* They are eſteemed very delicious when fried with fine flour, and occaſion, during the ſeaſon, a vaſt reſort of the lower order of epicures to the taverns contiguous to the places where they are taken at.

"There are various conjectures about this ſpecies, but all terminate in a ſuppoſition that they are the fry of ſome fiſh, but few agree to which kind they owe their origin. Some attribute them to the ſhad, others to the ſprat, the ſmelt, and the bleak. That they neither belong to the ſhad, nor the ſprat, is evident from the number of branchioſtegous rays, which in thoſe are eight, in this only three. That they are not the young of ſmelts is as clear, becauſe they want the *pinna adipoſa,* or rayleſs fin; and that they are not the offſpring of the bleak is extremely probable, ſince we never heard of the white bait being found in any other river, notwithſtanding the bleak is very common in ſeveral of the Britiſh ſtreams; but, as the white bait bears a greater ſimilarity to this fiſh than any other we have mentioned, we give it a place as an appendage to the bleak, rather than form a diſtinct article of a fiſh, which it is impoſſible to claſs with certainty. It is evident that it is not of the carp or cyprinus genus; it has only three branchioſtegous rays, and only one dorſal fin; and, in reſpect to the form of the body, it is compreſſed like that of the bleak. Its uſual length is two inches; the under jaw is longeſt; the irides ſilvery, the pupil black; the dorſal fin is placed nearer to the head than the tail, and conſiſts of about fourteen rays; the ſide line is ſtraight; the tail forked, the tips black. The head, ſides, and belly are ſilvery; the back tinged with green." Brit. Zool.

Dr. Shaw, in his "General Zoology," deſcribes the white bait as a ſpecies of the carp or cyprinus genus. It is obſerved, by this writer, that "this ſmall fiſh, which is extremely plentiful, at particular ſeaſons, in the river Thames, is ſuppoſed to be the young of ſome ſpecies of cyprinus, though it is not agreed to what ſpecies it ſhould moſt properly be referred." The white bait is introduced by Dr. Turton as a variety of the bleak, *cyprinus alburnus.* He deſcribes it as having the lateral line ſtraight. The general deſcription is to the following effect. "Pupil black; iris ſilvery; lower jaws longer; head, ſides, and belly ſilvery; back tinged with green; dorſal fin nearer the head than the tail, and with about fourteen rays; tail forked, the tips black." It will be proper to add, that no mention is made of this fiſh in the Gmelinian *Syſtema Naturæ,* and that Dr. Turton has inſerted it, to all appearance, on the authority of Mr. Pennant.

Our obſervations commenced with ſtating the white bait to be the genuine offspring of the ſhad, and conſequently of the clupea inſtead of cyprinus genus, as the preceding authors conſider it. This we ſhall have little difficulty in determining. To ſpeak with indeciſion on a point that admits of not the ſlighteſt doubt, would be ſuperfluous; when we deliver an opinion merely, it is becoming to expreſs it with diffidence; but ſurely diffidence and indeciſion are miſapplied to matters beyond the poſſibility of doubt, and ſuch is the fact preciſely with regard to white bait. Every circumſtance conſidered, we cannot avoid concluding that much of the prevailing errors reſpecting the white bait has originated from the incautious obſervations of Mr. Pennant on this ſubject; that this author never ſaw the white bait, and that ſucceeding naturaliſts, too implicitly relying upon his obſervations, have been inadvertently precipitated into thoſe errors, which the moſt caſual examination of the fiſh in queſtion would have enabled them to detect. If, however, contrary to this ſuggeſtion, Mr. Pennant ever did examine the fiſh, his ſpecimens muſt have been either in a moſt imperfect ſtate, or his inveſtigation of it unpardonably negligent. His figure conveys no juſt idea of the fiſh, and his critical animadverſions are laboriouſly intricate and defective. He tell us, for example, that the white bait "neither belongs to the ſhad nor the ſprat, as is evident from the number of branchioſtegous rays, which in thoſe are eight, in this (the white bait) only three." This remark is incorrect; the branchioſtegous rays were uniformly eight in number in at leaſt fifty ſpecimens we examined, with the view of aſcertaining the fact exactly. The number of thoſe rays determines at once that it cannot be of the cyprinus genus, which is diſtinguiſhed by having only three rays inſtead of eight. Mr. Pennant further remarks, that "it is impoſſible to claſs this fiſh with certainty," but in what reſpect this ambiguity conſiſts it is not for us to ſay. The white bait certainly poſſeſſes every criterion of the ſpecies as evidently as the parent, or full-grown fiſh; its outline is the ſame, the fins are alike; it exhibits the ſame ſerrations on the abdomen and cleft on the ſnout; and what is even remarkable in a fiſh of this ſmall ſize, the lateral range of duſky ſpots is perceptible through the beautiful ſilver ſcales, as in the larger fiſh; it exhibits, in a word, the moſt perfect but diminiſhed view of the common ſhad, not a ſolitary character excepted. Vide Donov. Brit. Fiſhes, pl. 98.

Harengus. Body without ſpots; lower jaw longer.

The common herring is a fiſh ſo generally known to every common obſerver, that we conceive it unneceſſary to offer an elaborate deſcription of it; the ſpecies is pretty accurately defined by the above character, which is that aſſigned to it by Linnæus in his "Fauna Suecica."

The importance of the herring to the inhabitants of Europe, and thoſe more particularly of the northern countries, is very great. The fiſhery of the herring, as may be naturally conceived, is very great. The Dutch who, in this reſpect, ſet an early example of induſtry to the reſt of Europe, were engaged in this fiſhery ſo long ago as the year 1164, and are ſaid to have carried it on for ſeveral centuries after, with the greateſt perſeverance and ſpirit. The method of pickling the herring, after the Dutch manner, is reported to have been diſcovered by William Beukelen, of Biervlet, near Sluys in Flanders, and his art, in a great meaſure, remains a ſecret to this day. The ſuperior excellence of the herrings pickled in this manner is generally allowed, and ſuch herrings bear a higher price than thoſe preſerved in any other way. The Britiſh pickled herrings are in little eſteem, except in our own country. Some attempts have been lately made to eſtabliſh a ſmall colony of Dutch fiſhermen on the coaſt coaft of Scotland, for the exprefs purpofe of pickling herrings in the fame manner as in Holland, but whether the laudable endeavours of thofe concerned will be ultimately fuccefsful, time alone can determine ; there feems to exift a general, and, no doubt, very unfounded prepoffeffion in the country, that they are ftill inferior to thofe pickled in Holland.

Many particulars related by authors, refpecting the periodical migrations of the herring from the northern regions towards the fouth of Europe, feem to admit of great difpute ; the beft informed ichthyologifts of the prefent time are inclined to think thofe accounts, in moft inftances, erroneous. It is fuppofed the herring, like the mackrel, remains, during the winter months, at no very great diftance from the fhores, which it moft frequents during the fpawning feafon ; the fame we have ourfelves obferved with regard to the fprat. In winter they inhabit the deepeft parts of the fea, or plunge beneath the foft mud at the bottom, from whence they rife at the fpring feafon, and approach the fhallows in order to depofit their fpawn in proper fituations. In proof of this, Bloch obferves, that herrings are found at almoft all feafons of the year about fome of the European coafts, and that the northern migrations, fuppofed by Pennant and others, are impracticable in the fhort period affigned by them, as the fifh, in its fwifteft progrefs, is utterly incapable of moving at a rate by any means fo rapid as the term allowed for thofe migrations would require. For this, and other reafons, Bloch is induced to think the long voyages of the herring exift only in the minds of its defcribers.

The herring is fuppofed to feed on marine worms, and the fmall fry of fifhes in general ; its greateft enemies are the various fpecies of whales, fome of which fubfift almoft entirely on this fifh.

Pilchardus. Nofe turned up ; dorfal fin in the centre of gravity ; fcales large and firm.

The pilchard is fomewhat allied in general appearance to the herring, but is thicker, or of a lefs compreffed form, the back more elevated, and the fcales very confiderably larger in proportion. It is alfo a fmaller fifh, rarely exceeding the length of eight inches. Pilchards, according to Dr. Borlafe, appear ufually in vaft fhoals off the Cornifh coafts, about the middle of July, and difappear again in the beginning of winter, though a few return again after Chriftmas. Their winter retreat is fuppofed to be the fame as that of the herring. The pilchard fifhery is a very productive concern on the coaft of Cornwall, where thofe fifh are cured for exportation. Oil is alfo extracted from them in great abundance.

Sprattus. Lower jaw longer than the upper ; dorfal fin about feventeen-rayed, belly ferrated.

The fprat inhabits the north of Europe, appearing at particular feafons in immenfe fhoals near the coafts ; it ufually fpawns in autumn.

Encrasicolus. Upper jaw longeft. Linn.

The general length of the anchovy is from three to four inches, or, at the utmoft, about four inches and a half ; though individual fpecimens have occurred of a ftill larger fize. The prevailing colour is filvery, with the back green.

This fifh is found in great plenty in the Mediterranean, Northern, and Atlantic feas, and, like the herring, is fuppofed to leave the deep receffes of the fea, and in fpring approach the fhores, for the purpofe of depofiting its fpawn. The great fifhery of anchovies is at Gorgona, a fmall ifle to the weft of Leghorn. They are taken in vaft quantities, and prepared for fale by falting and pickling ; the bones eafily diffolve in boiling. It is fuppofed to have been known to the ancient Greeks and Romans, who prepared from it a kind of garum for their table. The anchovy has been obferved, though very rarely, on the Englifh coaft. Vide Donov. Brit. Fifhes. See Anchovy.

CLUSES, in *Geography*, a town in the department of Leman, and chief place of a canton in the diftrict of Bonneville, feated by the fide of the Arve ; the place contains 2102, and the canton 10,330 inhabitants : the territory includes 190 kiliometres and 8 communes.

CLUSIA, in *Botany*, (fo called in memory of C. Clufius, or Charles de l'Ecclufe,) Balfam-tree. Linn. Gen. 1154. Schreb. 1584. Juff. 256. Vent. 3. 147. (Perepé Encyc.) Clafs and order, *polygamia monœcia*. Nat. Ord. *Guttiferæ*, Juff. Vent.

Gen. Ch. *Cal.* Perianth from four to fixteen-leaved, permanent, leaves concave, imbricated, the exterior ones gradually fmaller. *Cor.* Petals from four to fix, large, open, roundifh, larger than the calyx. *Stam.* Filaments from fix or eight, to a very great number, fimple, fhorter than the corolla. *Pift.* Germ ovate-oblong ; ftyle none, ftigma radiate, peltate, flat, obtufe, permanent. *Peric.* Capfule fpheroid, large, furrowed, from four to twelve-celled, opening from the fummit to the bafe into as many valves as there are cells, each terminated by a ray of the ftigma. *Seeds* numerous, fmall, covered with a fucculent pulp, affixed either to a central angular receptacle, or to receptacles adhering on the infide to the fummit of the valves.

Eff. Ch. Calyx from four to fixteen leaved. Petals from four to fix. Stamens generally very numerous. Stigma feffile, with diverging rays. Capfule from four to twelve-celled, opening longitudinally into as many valves. Seeds fmall, covered with a fucculent pulp.

Obf. All the flowers have ftamens and a piftil ; but in fome, the ftamens are abortive, in fome the piftil, and in others they are both perfect. All the fpecies are trees abounding in a vifcid juice, which becomes red when expofed to the air, and hardens into a gum or refin. In the female flowers, a nectary is formed by the coalition of the abortive anthers, including the germ.

Sp. 1. C. *rofea*, Linn. Sp. Pl. 1. Mart. 1. Poir. 1. Plum. Gen. 21. Jacq. Americ. 270. Pict. 231. (Cenchramidea, Pluk. Alm. 92. tab. 157. fig. 2. Catefb. Car. 2. tab. 99.) " Leaves veinlefs ; corollas fix-petalled." *Trunk* from twenty to thirty feet high ; branches fpreading. *Leaves* oppofite, quite entire, inverfely egg-fhaped, firm, coriaceous, even on their upper furface, marked underneath with oblique parallel nerves unconnected by veins, round, and fometimes a little emarginate at the fummit, narrowed at the bafe, on fhort peticles. *Flowers* large, rofe-coloured, axillary and terminal ; peduncles thick, fhort, fometimes fimple, more frequently two or three-flowered ; bractes fhort, obtufe, fcaly ; calyx-leaves fix, coloured, almoft round, concave, obtufe, open, fomewhat imbricated ; the two intermediate ones half the fize of the two interior ones, and twice the fize of the two exterior ones ; petals concave, very open, with a thick fhort claw ; ftamens very numerous, erect, awl-fhaped, the length of the germ, and furrounding it in two ranks ; in the female flowers, without anthers ; germ cylindrical, fhorter than the calyx, furrowed by the impreffion of the filaments ; ftigma with eight equal rays. *Capfule* greenifh, large, almoft round, obtufe, eight-celled, eight-valved. *Seeds* numerous, covered by a thick, foft pulp, attached to a very large central receptacle, the angles of which form the cells. A native of the Weft Indies, among rocks ; and it is alfo parafitic on the trunks or limbs of other trees, occafioned by birds fcattering the vifcid feeds, which take root like thofe of miffelto missleto, but not finding sufficient nutriment, the roots spread on the surface of the tree, till they find a decayed hole, or other lodgment, where there is a small portion of soil; the fertility of this being exhausted, a root is discharged out of the hole till it reaches the ground, though at forty feet distance; here again it fixes itself and becomes a much larger tree. The resin is used to cure sores in horses, and instead of tallow for boats. 2. C. *alba*, Linn. Sp. Pl. 2. Mart. 2. Poir. 2. Jacq. Amer. p. 271. tab. 166. Plum. Gen. 22. Icon. 87. fig. 1. "Leaves veinless; corollas five-petalled." In habit resembling the preceding species. *Leaves* also similar, except in being a little longer, not emarginate, and scarcely petioled. *Flowers* white, without scent, smaller and less elegant; calyx-leaves nine, in three ranks, of different sizes, as in C. rosea; petals twice as large as the internal calyx-leaves; filaments from five to eight, only half the length of the germ; germ a little shorter than the petals; stigma five or six-rayed. *Capsule* large, of a beautiful scarlet colour when ripe, five or six-celled, with the same number of valves. *Seeds* whitish, covered with a reddish pulp, attached to a large central receptacle. A native of Martinico. 3. C. *flava*, Linn. Sp. 3. Mart. 3. Poir. 3. Brown. Jam. 236. (Terebinthus; Sloan. Jam. 167. Hist. i. p. 91. tab. 200. fig. 1.) "Leaves veinless; corollas four-petalled." General habit, leaves and inflorescence similar to the two preceding. *Flowers* pale yellow; calyx almost quadrangular; composed of sixteen leaves in four ranks; the inner ones gradually increasing in size; petals egg-shaped, narrowed towards the claws, very thick, two larger than the others; stamens very numerous; filaments short, thick, nearly in four ranks round the germ; anthers with two separate lobes; germ very small; stigma thick, almost capitate, with four lateral appendages, twelve-rayed. *Capsule* twelve-celled, twelve-valved. *Seeds* numerous, attached to a very large, oblong, twelve-furrowed receptacle. It is said to vary in the colour of the flowers and fruit. A native of Jamaica, and of Cayenne, in South America, among rocks at the foot of mountains. 4. C. *retusa*, Poir. 4. Lam. Ill. tab. 852. "Leaves somewhat veined, egg-shaped, retuse; flowers six-petalled; fruit somewhat globular-compressed." *Leaves* six or seven inches long, and about three broad, opposite, petioled, very thick, completely retuse and round at the summit; marked with strong, transverse, parallel nerves, connected by very fine, scarcely perceptible, veins. *Flowers* axillary, towards the extremity of the branches, peduncled, often solitary; calyx-leaves eight, inversely egg-shaped, in two ranks; the outer ones not half the length of the others; bractes two, about the middle of the peduncles, and two others at the bifurcation, where there is more than one flower; short, egg-shaped, very thick, smooth, permanent; corolla much larger than the calyx; stamens very numerous, anthers simple, erect. *Capsule* globular, compressed at the two extremities, with at least sixteen or eighteen cells, and as many valves. A native of America. 5. C. *venosa*, Linn. Sp. 4. Mart. 4. Poir. 6. Plum. Gen. 21. Ic. 87. fig 2. "Leaves veined." Trunk more than thirty feet high. *Flowers* white; calyx-leaves four, roundish; two outer ones a little narrower, acute; petals four, egg-shaped, obtuse, very open, a little longer than the calyx; stamens very numerous; filaments straight, a little flattened; anthers erect, oblong; stigma five-rayed. Miller's plant, which seems to be a variety, has rose-coloured flowers, produced in long spikes at the end of the shoots. A native of the West Indies. 6. C. *sessiliflora*, Poir. 5. "Leaves inversely egg-shaped, somewhat veined; flowers sessile, clustered." *Stem* rugged, greenish. *Leaves* opposite, coriaceous, thick, sometimes emarginate, quite entire, narrowed at the base; petioles only two or three lines long, compressed, thick. *Flowers* small, axillary. A native of Madagascar, described from an imperfect specimen in the herbarium of La Marck, in which the parts of fructification could not be distinguished. 7. C. *sessilis*, Mart. 6. Forst. Fl. Aust. n. 391. "Leaves opposite, inversely egg-shaped and elliptic, quite entire, veined; flowers axillary, solitary, nearly sessile, four-petalled." A native of New Caledonia. 8. C *pedicellata*, Mart. 6. Forst. Flor. Austral. n. 390. "Leaves opposite, inversely egg-shaped, quite entire, veined; cymes axillary; flowers four-petalled. A native of Tongatabu.

Propagation and Culture. These plants are most advantageously imported in tubs from their native climates. They must be constantly kept in the stove, and sparingly watered, especially in winter. They may also be propagated by cuttings, which must be laid to dry for a fortnight or three weeks. The best time for planting them is in June or July, when the pots should be plunged into a hot-bed of tanner's bark. In winter they may be placed upon stands in the dry stove; but if they are plunged into the tan-bed in summer, their leaves will be larger and more beautiful.

C. *foliis venosis*, Fabric.—*Minor*, Rumph. See DECUMARIA *barbara*.

CLUSINA PALUS, in *Ancient Geography*, the name of a long marsh, formed by the waters of the Clanis, near Clusium.

CLUSINI FONTES, fountains of Italy, in Etruria, placed by the ancients near Clusium. They are now called "Bagni de S. Cantiano."

CLUSINI, a people of Italy, in Etruria; the *Clusini Novi* are placed by Pliny towards the sources of the Tiber, and he calls their town *Clusium Novum*; the *Clusini Veteres* are placed by the same author on a mountain, and he calls their town *Vetus Clusium*.

CLUSIUM, now *Chiusi*, a town of Italy, at a small distance to the west of Perugia, on the right bank of the Clanis. Its ancient name was "Camers." Its origin is traced to about the time of the siege of Troy; and some attribute its foundation to Clusius, son of Tyrrhenus, and others to Telemachus. In the time of the Romans it was considerable; and Porsenna held his court and was buried in this place. Pliny speaks of his tomb, and of a monument erected in honour of him, called the "Labyrinth." The Gauls besieged this place, but marched towards Rome without taking it. This place is now, on account of the insalubrity of the air, almost forsaken.

CLUSIUS, more properly DE L'ECLUSE, CHARLES, in *Biography*, a very eminent botanist, born at Arras, in the French Netherlands, February 19, 1526. He received the first rudiments of polite literature, with the knowledge of several modern languages, at Ghent; and afterwards bestowed some time upon the Greek and Latin classics at Louvain, where he likewise applied himself to the study of jurisprudence. He also took a degree in medicine; but it does not appear that he pursued either of these studies as a source of emolument. Having always had an ardent desire to visit foreign countries, he went to Germany at the age of 23; where he imbibed a taste for general science, especially geography and botany. He travelled into the south of France, but was called home by his father on account of the civil wars, about 1563. He afterwards found means to visit that kingdom again, as well as Spain, and great part of Portugal, chiefly with a view to the botany of those countries, which he has amply illustrated. He visited England at three several times. In all these journies he formed valuable acquaintances among the learned in his favourite science, who subsequently communicated their various discoveries to enrich his publications; his liberal, candid, and amiable disposition preserving him from all envy and rivalship. He not only collected and described a number of new plants, but made drawings of several with his own hand. In the year 1573, Clusius was invited to Vienna by the emperor Maximilian II., with whom, as well as with his son, afterwards the emperor Rodolphus II., he was in great favour, and was honoured by the former with the rank of nobility. He had always a great desire to visit Italy; but having three times been diverted from his purpose by various accidents, he concluded it was not the will of Providence that he should ever see that country, and gave up the design. In 1593, the 68th year of his age, Clusius was chosen professor of botany at Leyden, where he resided in great reputation till his death, which happened on the 4th of April 1609, in the 84th year of his age. He was honoured with a public funeral in St. Mary's church, Leyden, when a Latin oration in his praise was delivered by the rector of the university. He died unmarried. With respect to bodily health, Clusius was unfortunate beyond the usual lot of humanity. In his youth he was afflicted with dangerous fevers, and afterwards with a dropsy. He broke his right arm and leg by a fall from his horse in Spain, and dislocated, as well as fractured, his left ankle at Vienna. In his 63d year he dislocated his right thigh, which, being at first neglected, could never afterwards be reduced, and he became totally unable to walk. Calculous disorders, in consequence of his sedentary life, accompanied with colic and a hernia, close the catalogue of his afflictions. Yet his cheerful temper, and ardour for science, never forsook him, nor did any man ever enjoy more respect and esteem from those who knew him.

Clusius may be said to have held the botanical sceptre for a long course of years till his death. Although not, like his great contemporary, Conrad Gesner, a systematic genius, he was one of the best practical botanists. He discriminated plants very happily, and his histories of them are rendered interesting by innumerable remarks and anecdotes, which carry his readers along with him wherever he goes, to share his pleasures without his toils. When seated in his botanical chair at Leyden, his authority was respected on all hands, and all discoveries were laid at his feet. Our gardens are indebted to him for the cherry-laurel and horse-chesnut, now so common and so ornamental, which he received, among many other plants, from the imperial ambassador at the Porte, in 1576. All the rest of the cargo perished, but Clusius bestowed the greatest possible attention to preserve and increase these; for, unlike many selfish collectors, he delighted to disperse his treasures among those who took pleasure in their acquisition, and it is but just that his memory should be perpetuated along with those two beautiful trees, with which all botanists of taste ought for ever to associate his name, thus giving him a monument more lasting than brass or marble.

The principal publications of Clusius are the following:

1. "Rariorum aliquot Stirpium per Hispanias observatarum Historia," Antwerp, 1576, octavo, with above 220 wooden cuts, admirably executed. In several parts of this work, he considers the fructification as of primary importance for determining the genera of plants, a doctrine which had but recently been first advanced by Conrad Gesner, and Cæsalpinus.

2. "Rariorum aliquot Stirpium per Pannoniam, Austriam, et vicinas quasdam Provincias observatarum Historia," Antwerp, 1583, octavo, with above 350 wooden cuts, somewhat less elegant, as Haller observes, than those of the former work, but sufficiently good and original, as is the letter-press of both. The former is a treasure of the vegetable productions of the south of Europe, as the latter is of Alpine ones. Both are commodious and highly agreeable pocket-companions for the travelling botanist.

3. The foregoing were re-published, with the title of "Rariorum Plantarum Historia," in folio, at Antwerp, in 1601, with some additions of garden plants, an ample treatise on *fungi*, with cuts, some of Clusius's correspondence, and Pona's account of mount Baldus. This is the edition in common use, and most generally quoted.

4. "Exoticorum Libri decem," Antwerp, 1605, folio, with numerous cuts of animals, exotic fruits, and gums. The observations of Garcias ab Orta, Acosta, Monardez, and Bellon, form the basis of this work, to which Clusius has added many illustrations. An appendix of his own on rare plants is subjoined, in which is the first figure of the horse-chesnut in flower.

5. "Curæ Posteriores," Antwerp, 1611, folio. This posthumous work is generally bound with the last. It consists of a few excellent figures and descriptions of rare plants. The funeral oration of Clusius, with various poetical tributes to his memory, are commonly annexed to this volume, and among them a short account of his life from "Boissard's Portraits of Illustrious Men."

To this list may be added various translations and editions of other writers on Botany, or Materia Medica. A manuscript of Clusius on *fungi* is said to exist in the library at Leyden. Boissard. Haller's Bibl. Botan. Clusius's works. S.

CLUSIUS, or *Clusio*, in *Ancient Geography*, now *La Chiése*, a river of Italy, in Cisalpine Gaul; which bounded the country of the people denominated "Cenomani," according to Pliny.

CLUSTER, in *Agriculture*, a bunch or number of things of the same kind growing or joined together.

CLUSTER-*Sowing*, that method of sowing grain, in which a number of corns are placed in the ground together, or in clusters. See SOWING *of grain*.

CLUSTERS, a word provincially used, to imply the bunches or clumps in turnip crops, &c.

CLUSTER *of Stars*, in *Astronomy*. See NEBULA and STAR.

CLUSTER-*polype*. See POLYPE.

CLUTIA, in *Botany*. See CLUYTIA.

CLUTIA *androgyna*; Linn. Mant. See ANDRACHNE *fruticosa*.

CLUVERIUS, or CLUVIER, PHILIP, in *Biography*, a celebrated geographer, born at Dantzic in 1580. The earlier parts of his education he received under the eye of his father, who sent him to Leyden to finish his studies. Here he was intended to pursue the civil law, but showing a decided disposition for geographical studies, he was advised by Joseph Scaliger to devote himself chiefly to the advancement of that branch of knowledge. With this view he resolved to examine for himself the Low Countries; but in his way to Brabant, he was robbed, and obliged to return to Leyden. His father abandoned him to want, because he refused to pursue the course which he had marked out for him in the law; the young man, therefore, had recourse to the military life, and served in Bohemia two years. He was afterwards imprisoned, on account of a publication relating to state affairs. Upon recovering his liberty he resumed his geographical pursuits, and travelled into England, France, Germany, and Italy, for the purpose of making accurate observations of the countries which he meant to describe. He was every where received by literary and learned men, with all the respect due to his talents. He

spoke

fpoke with fluency ten languages, *viz.* the Greek, Latin, German, French, English, Dutch, Italian, Hungarian, Polish, and Bohemian. On his return to Leyden he taught with reputation, and died at the early age of 43 years. His principal works are, 1. "De Tribus Rheni Alveis;" 2. "Germania Antiqua;" 3. "Italia Antiqua, Sicilia, Sardinia, et Corsica;" 4. "Introductio in Universam Geographiam." Moreri.

CLUVESYECK, in *Geography*, a town of Germany, in the duchy of Holstein; 5 miles E.N.E. of Rendsburg.

CLUVIA, in *Ancient Geography*, a place of Italy, in the country of the Samnites, garrisoned by the Romans.

CLUYTIA, in *Botany*, (named by Boerhaave, in memory of Angerius Clutius, or, in his native language, Antgers Cluyt, professor of botany at Leyden. The name of the genus has usually been spelt Clutia; but professor Martyn has judiciously altered it to Cluytia, to make it more distinct, in pronunciation, from Clusia.) Linn. Gen. 1140. Schreb. 1526. Gært. 623. Juss. 387. Vent. 3. 489. (Clutelle; Encyc.) Class and order, *dioecia gynandria*. Nat. Ord. *Tricoccæ*, Linn. *Euphorbiæ*, Juss. *Tithymaloideæ*, Vent.

Gen. Ch. *Male. Cal.* Perianth five-cleft or five-leaved; leaves concave, spreading. *Cor.* Petals five, spreading very much, about the length of the calyx and alternating with its divisions; claws flat; scales (called by Linnæus exterior nectaries) five, small, trifid, spreading, opposite to the divisions of the calyx, placed in a circle within the petals, and about the length of the claws; glands (called by Linnæus interior nectaries) five, small, mellifluous at the tip, placed between the scales, opposite to the petals. *Stam.* five, situated on the upper part of the style, remote from the corolla, spreading horizontally; filaments short; anthers roundish, versatile. *Pist.* Germ none; style cylindrical, truncated, very long, bearing the stamens. *Female. Cal.* and *Cor.* as in the male, permanent; scales or exterior nectaries five, didymous, of the same size and situation as in the male; interior nectaries none. *Pist.* Germ roundish; styles three, bifid, reflexed, the length of the corolla; stigmas obtuse. *Peric.* Capsule globular, six-furrowed, scabrous, three-celled. *Seeds*, one in each cell, roundish, even-surfaced, with an appendage at the tip.

Eff. Ch. Calyx five-leaved or five-cleft. Corolla five-petalled. Styles, in the female flowers, three. Capsule three-celled. Seeds solitary.

Sp. 1. C. *daphnoides*. Lam 1. (Chamœlea; Burm. Afr. 120. tab. 44. fig. 2.) "Leaves nearly linear, narrowed towards the base, obtuse at the tip; younger ones tomentous on both sides; flowers solitary, erect." A shrub about two feet high, much branched; branches cylindrical, stiff; smaller ones leafy, cottony near the summit, tubercled below. *Leaves* almost sessile, near together, without any regular order, thickish, resembling those of Daphne Cneorum, but smaller and less smooth. *Flowers* axillary, peduncled, generally solitary; males smaller than the females and less erect. A native of Africa, communicated by Sonnerat. 2. C. *alaternoides*. Linn. Sp. Pl. 1. Mart. 1. Lam. 2. (Tithymalus; Pluk. Alm. 369. tab. 290. Chamœlia; Burm. Afr. 116. tab. 43. fig. 1. Alaternoides; Comm. Hort. 2. p. 3. tab. 2.) "Leaves nearly sessile, linear-lanceolate; flowers solitary, erect." Linn. "Leaves linear-lanceolate, mucronate, quite smooth, cartilaginous and scabrous at the margin." Lam. A shrub, about two feet high; Lam. (Six or eight; Miller.) *Stems* leafy, almost their whole length; branches numerous, on their upper part, commonly simple, angular. *Leaves* scattered. *Flowers* greenish-white, small, axillary, solitary, peduncled; males smaller, a little pendulous. A native of Africa. 3. C *polygonoides*. Linn. Sp. Pl. 2. Mart. 2. Lam. 3. (Chamœlea; Burm. Afr. 118. tab. 43. fig. 3.) "Leaves lanceolate; flowers axillary, very numerous." *Leaves* alternate, gradually narrowed to the summit, acute, smooth, quite entire. *Flowers* small, usually two together, pendulous. A native of the Cape of Good Hope. 4. C. *pulchella*, Linn. Sp. Pl. 3. Mart. 3. Lam. 4. Gært. tab. 107. Lam. tab. 835. (Frutex Æthiopicus; Comm. Hort. 1. p. 177. tab. 91.) "Leaves egg-shaped, quite entire; flowers lateral." A shrub, three or four feet high. *Stem* upright, branched at its summit, forming a handsome head; branches smooth, with a greenish bark. *Leaves* an inch broad, alternate, petioled, soft, finely dotted underneath. *Flowers* greenish-white, axillary, commonly several together; male ones smaller, on peduncles only three lines long; female, on peduncles longer than the petioles. Lam. *Capsule* pedicelled or sessile, globular, scabrous, with elevated points, three-furrowed, tricoccous; cocci of the substance of paper, gibbous on one side, angular on the other, semi-bivalved, the back of the valves separating spontaneously from the partitions; partitions membranous, permanent on the axis of the fruit, dark chestnut-coloured, shining, slightly serrated on the edges. *Receptacle* central; filiform, covered by the partitions which form six membranous roundish wings about the axis. *Seeds* dark chestnut-coloured, egg-shaped, smooth, shining, with a two-lobed white umbicular gland immediately below the tip on the inside. A native of Africa. 5. C. *lanceolata*, Mart. 10. Vahl. Symb. 2. 101. Forskal. Ægypt. 170. "Leaves elliptic-lanceolate; flowers lateral, tomentous." Nearly allied to the preceding, but differs in having the branches purple, and ash-coloured, villous at the top. *Leaves* broad-lanceolate, two inches long or more, without dots underneath, few above, and visible only with a magnifier. *Male-flowers* numerous, aggregate, axillary, on very short peduncles; female ones commonly solitary, peduncled; calyxes villous-tomentous. *Capsules* not dotted. A native of Ægypt. 6. C. *hirta*, Linn. jun. Supp. 432. Mart. 4. Lam. 9. Vahl. Symb. 2. 101. "Leaves wedge-shaped, smooth; flowers lateral, glomerate, hirsute." A shrub. *Branches* cylindrical, smooth, tubercled with the remains of fallen leaves, usually scattered, but sometimes three together. *Leaves* petioled, reticularly veined. *Flowers* nearly sessile; calyx rough with short hairs; petals oblong, minute, smooth; style trifid, involved in ash-coloured hairs. Found by Thunberg at the Cape of Good Hope. 7. C. *tomentosa*, Linn. Mant. 299. Mart. 5. Lam. 5. "Leaves elliptical, tomentous on both sides." A shrub, three feet high, much branched, upright, tubercled with the remains of fallen leaves. *Branches* cylindrical, pubescent. *Leaves* the size of those of thyme, sessile, rather acute. *Flowers* white, sessile, lateral solitary, longer than the leaves; calyx five-toothed, cottony on the outside; petals oval, the length of the calyx; stigma bearded. A native of sandy shores at the Cape of Good Hope. 8. C. *retusa*, Linn. Sp. Pl. 4. Mart. 6. "Leaves oval, retuse: flowers racemed, axillary." *Leaves* on short petioles, alternate, the size of those of beech, reflexed at the edge, with prominent transverse nerves underneath. *Flowers* very small; racemes axillary, quite simple near the ends of the branches; partial peduncles three or four, alternate, filiform; calyx-leaves acute; petals three-toothed; nectaries none, except a ring surrounding the receptacle; in the middle a column with five horizontal filaments, and versatile anthers. A native of the East Indies. 9. C. *squamata*, Lam. 6. (Scherunam-cottam. Rheed. Mal. 2. p. 23. tab. 16. Good. Rai. hist. 1623. Corni five forbi species; Bont. Jav. 103.) "Leaves elliptical, smooth above, pubescent and nerved underneath; flowers axillary, sessile,

sessile, squamose at the base." A shrub, ten or fifteen feet high; upper branches slender, almost filiform, leafy, pubescent towards the summit. *Leaves* alternate, on short petioles, entire; furnished underneath with lateral, oblique, parallel nerves, which are crossed by other smaller ones. *Flowers* axillary, not racemed, but sessile, and often clustered two or three together, supported by a small somewhat spungy knot, which is formed by the scales. *Capsules* egg-shaped, smooth, with three or four cells. A native of the East Indies, found by Sonnerat and Commerson. La Marck doubts whether it be not the retusa of Linnæus; but the descriptions are so inconsistent, that we have thought it best to keep them distinct, though the synonyms, quoted by Linnæus, probably belong to La Marck's plant. 10. C. *eluteria*, Linn. Sp. Pl. [illegible] Mart. 7. Lam. 8. Woodv. Med. Bot. Supp. Pl. 211. [illegible] Clif. 486. Croton; Brown, Jam. 347. n. [illegible] Pluk. a.m. tab. 220. fig. 5.) Seba Thes. 1. tab. 35. fig. 3. "Leaves cordate-lanceolate." A small tree, several feet high, with numerous branches; bark of the branches brown and smooth; that of the trunk externally more white and rough. *Leaves* alternate, on long petioles, obtuse, bright green above, paler underneath. *Flowers* both of the male and female plants in spikes, whitish, with all the characters of the other species; but it is necessary to observe that Dr. Woodville does not notice the number of stamens, which according to Linnæus are ten, and render the real genus of the plant uncertain. There is much confusion with respect to it and croton cascarilla of Linnæus; the latter of which, a native of the Spanish main, has been supposed by many to afford the medicinal bark, called cascarilla. But Dr. Woodville positively asserts, that this drug is the produce only of cluytia eluteria, and is brought to Europe solely from the Bahama islands. This description and figure are taken from a specimen in the herbarium of Sir Joseph Banks. In the same plate he has figured a branch sent from Jamaica by Dr. Wright, under the name of croton elutheria, which, in his account of medicinal plants of Jamaica, he says, is the same as the cascarilla, or elutheria; but it appears from Dr. Wright's specimens in the herbarium of the president of the Royal Society, that his plant is dioicous and truly a cluytia, differing from that of the Bahama islands in having broader and more obtuse leaves. According to Lewis, the cortex cascarillæ is imported into Europe from the Bahama islands, particularly from that which is called elutheria, in curled pieces, or rolled up into short quills about an inch in width; exhibiting, when broken, a smooth, close, blackish-brown surface. Freed from its outer whitish coat, which is insipid and inodorous, it has a light agreeable smell, and a moderately bitter taste, accompanied with a considerable aromatic warmth. Its virtues are partially extracted by water, and totally by rectified spirit. Distilled with water it yields a greenish essential oil, of a very pungent taste, and of a fragrant penetrating smell, more grateful than that of cascarilla itself. See CASCARILLA. 11. C. *stipularis*, Linn. Mant. 127. Mart. 8. Lam. 7. "Leaves oval, tomentous underneath." *Branches* zigzag, tomentous. *Leaves* rather large, quite entire, on short petioles; stipules egg-shaped, acute, the length of the petioles. *Flowers* dark purple, axillary, sessile, not longer than the stipules; calyx one-leafed, campanulate at the base, with five acute divisions, permanent; petals roundish, very short, alternately with the divisions of the calyx; style columnar, trifid, stamens five, fertile and horizontal. A native of the East Indies. 12. C. *acuminata*, Linn. Supp. 432. Mart. 9. Lam. 10. "Herbaceous; leaves egg-shaped, smooth, obtuse, with a point; flowers axillary, solitary." A native of the Cape of Good Hope. It resembles andrachne telephoides.

Propagation and Culture. C. alaternoides and C. pulchella, are easily propagated by cuttings during any of the summer months. The pots should be plunged into a very moderate hot-bed, till the cuttings have taken root. The plants should afterwards be put separately into small pots, and kept in the open air, in a sheltered situation, till October or later, if the weather prove mild. In winter they require only the shelter of the green-house, without artificial heat; but should occasionally be allowed free air, they will otherwise grow mouldy and perish. C. eluteria may also be propagated by cuttings during the summer, which should be kept in a dry place for a few days before they are planted. It will live through the winter in an airy glass-case, but must be sparingly watered. In summer it requires only to be screened from heavy rain.

CLWYDD, *Vale of*, in *Geography*, a singularly beautiful and fertile vale in North Wales, which extends northward from the termination of the Berwin hills, near Llangollen, by Ruthyn and Denbigh, to the sea beyond St. Asaph. The breadth of this vale is about three miles, and the length near thirty, and through almost the whole of it the two little rivers of the Clwydd and the Elwy run parallel to each other. It is separated by a ridge of mountains from the dreary wastes which encompass it; there is neither mountain nor rock to be seen in any part of it, after you turn your back upon Rudland; the hills on one side of it rise very gradually by gentle ascents: most of them are cultivated quite to their summits, others half-way up; and when the tops are not enclosed, they are a fine grassy down, and shaded and enlivened with wood. This vale abounds with rich enclosures, farm-houses, gentlemen's seats, pleasant villages; and its three towns, Ruthyn, Denbigh, and St. Asaph, stand in fine situations, about the distance of six miles from one another.

CLYDE, a large river in Scotland, inferior only to the Tay. The parent stream originates from Clydeslaw, in the parish of Crawford, one of those stupendous hills that separate the district of Annandale from Lanarkshire, near the sources of the Annan and the Tweed. After passing through, and thus dividing the county of Lanark, almost 55 miles, the Clyde enters the Frith of Clyde opposite to the district of Carval and the island of Bute, in Argyleshire. It is navigable for small craft only as far as Glasgow, and 6 miles below that city at Dalmure-burnfoot, the great canal from the Forth joins the Clyde. See CANAL. Part of Lanarkshire receives the name of Clydesdale, or Stathclyde, from this river, which it renders more fertile than any other portion of Scotland, and extremely romantic, through its numerous cascades. Twenty miles from Clydeslaw, the valley contracts, the banks become steep, and the gradual declinations on each side of the rivers are adorned with many handsome seats, the residences of gentlemen who have highly cultivated their lands, and planted the best descriptions of fruit-trees, which yield abundantly; and their rich meadows are covered with excellent flocks. Bonniton fall, or *linn*, derived from the Gaelic word "leum," *leap*, or *fall*, is so termed from an elegant mansion named Bonniton-house, situated near it; a short and romantic walk on a projecting rock, exhibits the fall of the river over a precipice 12 feet in height, into a hollow den, as Mr. Lockhart expresses it in the statistical account of Scotland, producing a pleasing contrast of foam and mist, with the placid surface above, where the Clyde emerges from beautiful groupes of forest-trees. After this descent, the stream rushes with angry impetuosity over a bed of rocks, bounded on either side with crags resembling ancient walls, from which wild birds fly in rapid succession; half a mile below, is the Corralinn, (derived from an estate and castle on one of the banks). The scenery of this neighbourhood is extremely grand, but the cascade, as viewed from seats placed in various parts of the walks, grouped with tremendous rocks, the castle, a corn-mill on a rock below, and rendered more sublime by the roar of the water rushing into an abyss, is truly astonishing." Sir James Carmichael, of Bonniton, erected a pavilion on the summit of a bank, in 1708, which affords a full view of the linn, and a mirror placed in the uppermost room, exhibits the cataract by reflection, as if it were on the point of overwhelming the spectator. The descent of the Clyde is said to be 84 feet, but there are three inconsiderable breaks in the fall. The mist from this prodigious body of water ascends to a very great height, and a perpetual rainbow glides, during the shining of the sun, from place to place, as the air acts on particles of the fluid. A third linn has obtained the name of Dundaff, or Black-cattle leap, probably from its vicinity to some fortress now forgot, which seems to be corroborated by the tradition, that denominates a rock the patriot Wallace's *chair*, or place of concealment from the English. Trouts frequently leap up this fall, which is about three feet high. New Lanark, a village, and four cotton-mills, are situated near Dundaff linn. Stonybyres linn, receives its name from Stonebyres, an estate in the possession of Daniel Vere, esq. This cataract, which is 80 feet in height, and 2 miles below Corra linn, terminates the progress of the salmon towards the source of the Clyde, but their attempts to ascend it during the spawning season, are incessant; nor is the horse-muscle, or pearl-oyster, though plentiful below the linn, ever found above it. The banks and precipices termed "Cartlane-craigs," are said to be nearly 400 feet higher than its level; and at the bottom flows the Mouss, a remarkable stream, which penetrates the hill of Cartlane, and the solid rock, in preference to a more convenient course on its very borders. The Clyde, having passed Lanark, proceeds to Hamilton and Glasgow, receiving several tributary streams, particularly the Avon, and the north and south Calders; besides which, the Leven enters it at Dumbarton, and the Carl near Renfrew; by these means the Clyde expands to the breadth of 2 miles opposite Newport, Glasgow, but the Channel alone is navigable by vessels of considerable burthen; below Greenock it enters the Frith of Clyde. Mr. Lightfoot, who explored the borders of this beautiful river, discovered some uncommon plants, which he has described in his "Flora Scotica," but the only mineral found in the neighbourhood, is spatum ponderosum, veins of which intersect the rocks. There are several small bridges on the Clyde, and one of magnificent design at Glasgow.

There is a light-house for the benefit of this navigation, on Little Cambray island, opposite to the south end of the Isle of Bute. The tide flows in this river to some distance above Paisley. The Ayr rail-way communicates with this river near the town of Ayr. An act passed 46 Geo. III. for making and maintaining water-works for supplying the town of Glasgow with water from this river. In 1806, 46 Geo. III. an act passed for the Glasgow and Saltcoats canal, to connect with this river at Ardrossan harbour. Mr. Thomas Telford, the engineer, is employed on both these works.

Clyde and Forth *Canal*. See *Forth* and *Clyde* in our article Canal.

CLYDON, from κλυζω, *I cause to fluctuate*; in *Medical Writers*, is used for the fluctuation of food taken into the stomach, arising from the laxity or weakness of its fibres, and of the abdominal muscles.

CLYMANT, a term used by some heralds to express a goat standing on his hind legs.

CLYMENE, in *Fabulous History*, the name of several females, the principal of whom were the following; viz. a daughter of Oceanus and Tethys, and mother, by Iapetus, of Atlas, Prometheus, &c.:—a nereid, and mother, by Jupiter, of Mnemosyne:—daughter of Oceanus, and mother, by Apollo, of Phaeton, &c.:—the mother of Homer, &c.

CLYMENEIDES, an appellation of the sisters of Phaeton, derived from the name of their mother.

CLYMENUM, in *Botany*, hispanicum, siliqua articulata, et siliqua plana, Tourn. See Lathyrus *articulatus*, and Lathyrus *clymenum*.

Clymenum *bithynicum, siliqua singulari*, Boerh. See Vicia *bithynica*.

Clymenus, in *Mythology*, a surname of Pluto.

CLY-MORE, a great two-handed sword, formerly used by the Highlanders. It was double-edged, and about two inches broad, or about one fifth of an inch broader than the ancient Roman gladius. The length of the blade of the cly-more was about 3 feet 7 inches; and that of the handle about 14 inches. It had a plain transverse guard of about a foot; and the weight of it was about six pounds and a half. These swords are supposed by some to have been the original weapons of the English, from the circumstance of the figure of a soldier's being found with one of them among the ruins of London, after the great fire in 1665. Such a sword must have been a very bad and inconvenient weapon, calculated only for giving a falling stroke, and that, too, at some distance, and must have been useless against a large shield; and such a sword as the Roman gladius, which was two-edged and sharp-pointed, peculiarly fitted for stabbing, and not above fifteen inches long in the blade.

CLYNDEE *Collieries*, in Langevelach parish, near Swansea in Glamorganshire, in South Wales, are works, belonging to Lockwood and Co., and famous for the under ground canal, which conducts to them, being a branch from the Swansea canal, in Morristown, about 3 miles above Swansea. This canal proceeds about 1000 yards in a north-west direction into the hill, along a tunnel 8½ feet high and 5 feet wide, for 4-ton boats; from over this canal-tunnel, a branch of under-ground rail-road, of half a mile long, proceeds along the Clyndee vein of coals, with numerous shorter branches of rail-road, to the present workings of coals. The communication between the canal and rail-road is made, by means of a perpendicular pit or shaft about 20 fathoms deep, through which the coals are let down in baskets of about 7 cwt. each, to be tipped or emptied into the boats below. The mode in which the descent of these baskets is regulated, is curious and singular: the rope, which connects the descending full basket and the ascending empty basket, winds over a horizontal roller, which connects by means of a toothed wheel with the upright shaft of a regulator, consisting of boards or arms which lave in the water of a round cistern or well, about 8 feet diameter, provided and constantly supplied with water to the requisite height, by means of pipes and cocks which bring in or let out water, whenever the coal-baskets are intended to descend slower or faster. This simple and effectual mode of regulating, or rather of destroying, power in machinery, was contrived by Mr. William Robert, a carpenter in the employ of Lockwood and Co. and was erected in the year 1793; notwithstanding

ſtanding which, Mr. Anthony George Echardt, in a patent dated 31ſt of January 1795, included this as his invention, and propoſes to apply it for regulating mills, to be worked by men, walking on the outſide or top, nearly of large cylindrical wheels.

CLYOQUOT, in *Geography*, a ſound or bay on the N.W. coaſt of America, weſterly from Berkley's ſound.

CLYPEA, or CLUPEA, a town of Africa, in the preſent kingdom of Tunis, the *Aſpis* of the Grecians, is built upon a ſmall promontory, the Taphitis of Strabo, which being in the figure of a ſhield or hemiſphere gave occaſion to the name. It is five leagues S.E. from the promontory of Mercury or Cape Bon. It is called by Livy, Mela, and Pliny, *Clupea*; by Polybius, Appian, and Agathemerus, *Aſpis*; but by Solinus and the Itinerary, *Clypea*. According to Silius Italicus and Solinus, it was built by the Sicilians; and they add, that its founders called it Aſpis. Strabo repreſents Clupea and Aſpis as one city; but Ptolemy erroneouſly diſtinguiſhes them, and places the cape of Mercurii promontorium between them. This was the firſt place which the Romans took in Africa, in the firſt Punic war. It was formerly an epiſcopal ſee. Nothing now remains of this ancient city, for the caſtle is a modern ſtructure: and what they now call *Clybea* is a collection of miſerable huts or cottages, about the diſtance of a mile from the ſpot where the old city ſtood.

CLYPEARIA, in *Botany*, alba; Rumph. Burm. See ADENANTHERA *falcata*.

CLYPEOLA, (diminutive of Clypeus, a ſhield, ſo called from the ſhape of the ſilicle.) Linn. gen. 807. Schreb. 1082. Willd. 1231. Gært. 819. Juſſ. 240. Vent. 3. 107. (Jonthlaſpi; Tourn. 99.) Claſs and order, *tetradynamia ſiliculoſa*. Nat. Ord. *Siliquoſæ*, Linn.

Gen. Ch. *Cal.* Perianth four-leaved; leaves ovate-oblong, permanent; Linn. (caducous; Lam.) *Cor.* Petals four, oblong, entire. *Stam.* Filaments ſix, ſhorter than the corolla; anthers ſimple. *Piſt.* Germ roundiſh, compreſſed; ſtyle ſimple, ſtigma obtuſe. *Peric.* orbicular, flat, compreſſed, very ſlightly emarginate, erect, deciduous, two-valved. *Seeds* orbicular, ſolitary.

Eſſ. Ch. Silicle emarginate, orbicular, compreſſed, flat, deciduous.

Sp. 1. C. *jonthlaſpi*, Linn. Sp. Pl. 1. Mart. 1. Lam. 1. Willd. 1. Gært. tab. 141. Lam. Ill. tab. 560. fig. 1. (Thlaſp. clypeatum, ſerpylli folio; Bauh. Pin. 107.—Jonthlaſpi: Col. Ecphr. 1. p. 281. tab. 284. Tourn. 210.) Annual treacle muſtard, or buckler muſtard. "Annual; ſilicles orbicular, one-celled, one-ſeeded." *Stems* about five or ſix inches high, ſlender, weak, almoſt ſimple, cloathed with ſhort whitiſh hairs. *Leaves* linear-ſpatula-ſhaped, ſmall, alternate, ſeſſile, glaucous, with minute ſtars of hairs on the ſurface. *Flowers* yellow, ſmall, the ſize of the calyx; in a ſmall terminal ſpike. *Silicle* pubeſcent, ſurrounded by a paler and finely ciliated edge, not opening ſpontaneouſly, but eaſily diviſible into two very thin membranous valves. *Receptacle* none, except a capillary umbilical cord, ſpringing from the margin of one valve, and extending to the centre of the cell. *Seed* elliptic, compreſſed, ſmooth, of a tawny colour. Gært. A native of the ſouth of France, Spain, and Italy. Villars doubts whether it be different from alyſſum minimum of Linnæus. Its filaments have a tooth above the baſe, as in moſt of the alyſſums. Willdenow has made this appendage, the leading eſſential character of that genus, but has, notwithſtanding, admitted maritimum and ſome other ſpecies, which he himſelf acknowledges to have perfectly ſimple filaments. 2. C. *tomentoſa*, Linn. Mant. 92. Mart. 2. (Alyſſum orientale. Ard. Spec. 2. p. 32. tab. 15. fig. 1. Lam. 9. Willd. 11.) Hoary treacle muſtard. "Perennial; ſiliques orbicular, two-celled; one ſeed in each cell." *Root* woody, branched ſtems ſhrubby, diffuſe; leaves hirſutely hoary; lower ones three inches long, half an inch broad, ovate-oblong, ſinuated; ſtem ones alternate, ſeſſile, linear-lanceolate, entire, or finely toothed. *Flowers* yellow, longer than the calyx, terminal and axillary, at firſt in a kind of umbel, but afterwards panicled. *Silicles* inverſely heart-ſhaped, alternate, peduncled. Firſt obſerved in the Levant by Tournefort; cultivated at Venice in 1755 by Arduini, from ſeeds ſent by Leonard Seller. 3. C. *maritima*, Linn. Sp. 2. Mart. 3. (Alyſſum maritimum; Lam. 8. Willd. 2. A. halimifolium; Hort. Kew. 2. 381; Bot. Mag. 101. Thlaſpi; alyſſon dictum maritimum; Bauh. Pin. 107.) Sea treacle muſtard or clowns muſtard. "Perennial; ſilicles two-celled, egg-ſhaped; one ſeed in each cell." *Stems* ſhrubby, much branched, diffuſe, evergreen. *Leaves* linear-lanceolate, quite entire. *Flowers* white, darker in the middle, reſembling thoſe of water-creſſes, with an agreeable honey-like ſmell, calyx deciduous; petals inverſely egg-ſhaped; filaments dark purple, toothleſs; anthers yellow. A native of the coaſt of the Mediterranean. In England, where it is uſually ſown in the rich borders of the garden, it grows ſo luxuriantly, that the ſtems, becoming juicy and tender, are generally deſtroyed by our froſts. It thus becomes an annual from peculiarity of circumſtance. Tournefort, Arduini, La Marck, Gærtner, Juſſieu, Ventenat, and Willdenow, all agree in referring the laſt two ſpecies to alyſſum, on account of their two-celled ſilicle, which Gærtner makes an eſſential character of alyſſum; a circumſtance which we cannot but think fully ſufficient to conſtitute a generic diſtinction; but as they have not been taken up in our firſt volume, we found it neceſſary to introduce them here.

CLYPEOLA *alliacea*, Arduin. Lam. See PELTARIA *alliacea*.

CLYPEOLA *alyſſoides*, Crantz. See ALYSSUM *calycinum*.

CLYPEOLA *annua ſiliculis bilocularibus diſpermis*, Sauv. See ALYSSUM *campeſtre*.

CLYPEOLA *didyma*, Crantz. See BISCUTELLA *lævigata*.

CLYPEOLA *montana*, Crantz. See ALYSSUM *montanum*.

CLYPEOLA *ſiliculis bilocularibus tetraſpermis*, Hort. Clif. See ALYSSUM *calycinum*.

CLYPEUS, or CLYPEUM, *Buckler*; a piece of defenſive armour, which the ancients uſed to carry upon the arm, to ſecure them from the blows of their enemies.

The figure of it was either round, oval, or ſexangular: in the middle was a boſs of iron, or of ſome other metal, with a ſharp point. See SHIELD.

CLYSMA, in *Ancient Geography*, a town and fortreſs of Egypt, ſituated at the bottom of the gulph of Heroopolis, according to Ptolemy, who, as well as the table of Peutinger, diſtinguiſhes this town from Arſinoe. Euſebius ſays expreſsly, that at Clyſma the Iſraelites paſſed the Red Sea. F. Calmet ſays, that this place, in modern times, is called *Colſum*.

CLYSSUS, a term uſed by the old writers in *Chemiſtry* and *Alchemy*, is defined, by Macquer, to be the vapours that ariſe from the detonation of nitre with any inflammable ſubſtance, &c. The clyſſus of nitre is the vapours from nitre and charcoal; the clyſſus of ſulphur, thoſe from ſulphur and nitre, &c. The term is now obſolete.

CLYSTER, or GLYSTER, in *Medicine*, Enema. A clyſter is a liquid medicine applied by injection up the rectum, and is a very ancient, and, in many caſes, a very important form of medicine, though leſs frequently employed in this than

than in many other countries, where medicine is practifed as a fcience.

Clyfters are applied either by a large fyringe which holds from one to two or more pints of liquid; or, in private practice, generally by means of a fmall ivory pipe faftened to, and opening into the middle of, a hog's bladder. To ufe it, firft ftop, with a fmall cork, the end of the pipe which opens into the bladder, then pour into the bladder the liquid intended to be thrown up, and tie it tight that none may fpill out. Then lay the patient on his belly, and introduce the pipe (previoufly oiled) for an inch or two into the rectum, draw out the cork, which may be eafily done through the folds of the bladder, and, by preffing gradually on the bladder, all the liquid will readily pafs up into the rectum. A perfon may readily perform this office for himfelf when ufed to it. The direction in which the pipe is to be introduced is parallel to the facrum, being that of the courfe of the lower part of the rectum to the anus.

Clyfters are ufed for feveral purpofes. Moft commonly they are purgative, and moft of the liquid cathartics taken by the mouth are alfo ferviceable as clyfters, obferving that confiderably larger dofes may be fafely ufed by injection. A pint of decoction of chamomile flowers with Glauber's falt, or thin gruel and falt, electuary of fenna and milk, or caftor oil made into an emulfion with egg, are very ufeful mild cathartics, which may be employed in this way, and many others might be enumerated. It is of advantage to employ fome emollient fubftance, combined with the purgative, to defend the inteftine in fome meafure againft the acrimony of the medicine. Thus, if the electuary of fenna is ufed, it may be conveniently rubbed up with a little oil, and the whole will then mix uniformly with milk or any other liquid.

When clyfters are employed as purgatives, it muft be remembered that they cannot pafs higher up than the valve of the colon, and confequently that they can only act directly upon the large inteftines. Therefore, they can feldom entirely fupply the place of purgatives by the mouth, which pafs through and excite the whole inteftinal canal; but they prove moft ufeful auxiliaries, particularly in thofe cafes of inteftinal diforder that are attended with much vomiting and irritability, where, befides emptying the lower bowels, they act as topical fomentations, and very often induce eafe and fleep when other methods fail. In fuch cafes, therefore, they fhould be in pretty large quantity, not very ftimulating, and as warm as the patient can bear them.

Glyfters are alfo of fingular fervice in checking that extreme and painful irritation of the rectum, that attends long continued diarrhœa and dyfentery. In thefe diforders the great fuffering of the patient is the inceffant tenefmus, and difcharge of bloody mucus from the inteftine, with extreme pain and irritation. This is often wonderfully relieved by a glyfter made of thin ftarch, or linfeed tea, or any other mild mucilage, mixed with a few drops of laudanum. The quantity of liquid injected in this cafe fhould be but fmall, that it may not ftimulate the inteftine merely by its bulk, but the dofe of any opiate, given by glyfter, may in general be three or four times the quantity which, under fimilar circumftances of age, conftitution, &c., would be given by the mouth.

We may mention a few other fpecific purpofes for which glyfters have been employed with advantage.

As vermifuges they have a peculiar and local ufe, where the worms are lodged in the lower inteftines, particularly as very highly ftimulating medicines are often required to diflodge thefe troublefome animals, which, if given by the mouth, might produce a good deal of inconvenience and irritation.

Tobacco infufion is given by way of glyfter in ftrangulated hernia, to bring on that extreme ftate of faintnefs and relaxation which is moft favourable to the reduction of the hernia.

In uterine or inteftinal hæmorrhage, reftringent clyfters, and particularly iced water, are fometimes of powerful ufe in checking thefe alarming accidents.

Afafœtida infufion, and other antifpafmodics, were formerly often injected in hyfteria, and other complaints for which this clafs of remedies is employed, but this is little ufed at prefent.

Turpentine mixed with a watery liquid, by the intermede of egg, is often given by clyfter, and in this way it powerfully acts both on the bowels and kidnies, giving that peculiar fmell to the urine which attends the internal ufe of this remedy.

Laftly, nutritive fubftances are fometimes given in this way, when, from conftriction or wounds in the œfophagus, nothing can be taken into the ftomach. This is, doubtlefs, a very imperfect method of fupplying the wants of nature, as comparatively only a fmall quantity of the abforbents open into the lower inteftines, but cafes have occurred in which life has been fupported by this means for many days. The fubftances to be injected in thefe cafes, are any of the animal or vegetable liquids and infufions which are known to afford the moft nutriment, fuch as ftrong broths, milk, jellies, and the like.

CLYSTRUS, in *Ancient Geography*, a town of Afia, fituated near the fea, in a diftrict of mountainous Cilicia, according to Ptolemy.

CLYTÆ, a people of Macedonia, who furnifhed excellent nitre. Pliny.

CLYTEMNESTRA, in *Fabulous Hiftory*, the daughter of Jupiter, or of Tyndarus, king of Sparta, by Leda, and wife of Agamemnon. While this prince was at the fiege of Troy, fhe had an intrigue with Ægifthus, whom fhe engaged to murder Agamemnon on his return. His fon Oreftes, however, avenged the death of his father, by killing Ægifthus, together with his mother Clytemneftra. See AGAMEMNON and ORESTES.

CLYTHENESS, in *Geography*, a cape of Scotland, in the German Ocean, on the fouth-eaft coaft of the county of Caithnefs. N. lat. 58° 14'. E. long. 0° 10'.

CLYTIA, or CLYTIE, in *Fabulous Hiftory*, daughter of Oceanus and Tethys, was beloved by Apollo; but afterwards deferted by him, in confequence of an amour with Leucothoe, her fifter. Clytia difcovered the fecret to her rival's father; and on this account Apollo treated her with contempt and abandoned her; fo that fhe languifhed, and, by continually gazing on the fun, was changed into a funflower, which ftill turns towards the fun, in token of her love.

CLYTIUS, one of the giants flain in the war againft Jupiter, by Hecate; or, according to Apollodorus, by Vulcan.

CLYTORIS, a beautiful virgin of Theffaly, deflowered by Jupiter, who, for this purpofe, affumed the form of an ant.

CLYTUS, one of the Centaurs.

CNACADION, in *Ancient Geography*, the name given by Paufanias to one of the three mountains, between which was fituated the town of Las. This mountain was in Laconia.

CNACALON, or CNACALUS, a mountain of the Peloponnefus, in Arcadia. Diana had a temple on this mountain, and was worfhipped in it under the appellation of "Cnacalefia." Paufanias.

[illegible]USON, a town of the Peloponnefus, in Arcadia, [illegible] according to Paufanias (l. viii. c. 27.), was one of the colonies founded under the aufpices of Epaminondas.

C[illegible]CLEUS, fuppofed to be the *Cnacion* of Plutarch, a river of the Peloponnefus, in Laconia.

CNEMIS, a town of Greece, upon the fea-coaft in the Locride, according to Pliny. It is called *Cnemides* by Mela, Ptolemy, and Strabo; the latter of whom fays, that it was a fortified place, and fituated oppofite to the promontory C[illegible], in the ifle of Eubœa.—Alfo, a mountain of the Lo[illegible], oppofite to the fame ifland, from which the Locrii Epicnemides, who inhabited its vicinity, derived their appellations.

CNEMODACTYLÆUS, in *Anatomy*, a mufcle, otherwife called EXTENSOR *tertii internodii digitorum*.

CNEORUM, in *Botany*, (Κνεωρον; Hippoc. Theophraft. Cneorum; Plin. Derivation unknown.) Linn. Gen. 48. Schreb. 65. Willd. 81. Juff. 369. Vent 3. 443. (Chamælea; Tourn. 421. Gært. 441. Cameleé; Encyc.) Clafs and order, *triandria monogynia*. Nat. Ord. *Tricoccæ*, Linn. *Terebintaceæ*, Juff. Vent.

Gen. Ch. *Cal.* very fmall, three-toothed, permanent. *Cor.* Petals three, oblong, erect, three times the fize of the calyx, equal, deciduous. *Stam.* Filaments three, awl-fhaped, fhorter than the corolla; anthers fmall. *Pift.* Germ. fuperior, obtufe, triangular; ftyle erect, the length of the ftamens; ftigma trifid, fpreading. *Peric.* Berry dry, hard, globularly three-lobed, tricoccous; cocci two-celled, two-feeded, (three-berried drupe; Gært.) *Seeds* folitary, con[illegible].

Eff. Ch. Calyx three-toothed. Petals three, equal. Berry dry, tricoccous.

Sp. C. *tricoccum*, Linn. Sp. Pl. Mart. Lam. Willd. Gært. tab. 70. Lam. Ill. tab. 27. (Chamælea tricoccos; Bauh. Pin. 462. Cam. Epit. 973.) Widow wail, or fpurge olive. A fmall ever-green fhrub, about two feet and a half high; branches compact, well garnifhed with leaves, cylindrical, fmooth, greenifh. *Leaves* alternate, feffile, elongated, entire, narrowed at the bafe, a little enlarged towards the fummit, fmooth, rather thick, with a ftrong vein or rib along the middle. *Flowers* pale yellow, fmall, axillary, on fhort peduncles, often folitary, fometimes two or three together. Lam. *Fruit* tricoccous, or confifting of three fmall-berried drupes, gibbous on one fide, angular on the other, joined at a common axis, dark brown when ripe; flefh thin, green; fhell bony, thick, nearly globular, wrinkled, marked on the inner fide with a furrow and umbilical hole, two-celled, without valves; one of the cells placed behind the other, both of them at the feat of the radicle, divided by a very flender partition, fo that the upper part of the fhell appears four-celled. *Receptacle common* filiform, terminated by the ftyle; *proper* confifting of fmall umbilical cords reaching from the axis of the fruit to the feeds. *Seeds* one in each cell, very fmall, egg-fhaped, doubled together like a worm, white, with a brown caruncle at the infertion of the umbilicus. Gært. A native of the fouth of Europe in dry, rocky foils. CNEORUM. See CONVOLVULUS, and DAPHNE.

Propagation and Culture. This ornamental little fhrub is hardy enough to bear the cold of our winters, provided it be not rendered too luxuriant by being planted in a very rich foil. Its feeds fhould be fown in autumn, foon after they are ripe, in a bed of common earth, and covered half an inch deep. In the autumn following the plants may be removed where they are to remain. They flower in March, and produce a frefh fucceffion through the whole of the fummer. The leaves and fruit are acrid, cauftic, and violently purgative.

CNEPH, in *Mythology*, denoting *good*, by way of eminence, an appellation under which the ancient Egyptians, particularly in the vicinity of Thebes, honoured the beneficence of the Creator, as they adored his power under the name of *Phtha*, and his wifdom under that of *Neith*. "The priefts of Egypt," fays Eufebius, (Evang. Præp. l. 3.) "call Cneph the architect of the univerfe." Strabo mentions his temple, built in the ifle of Elephantis. The fymbol of this god, or attribute of the divinity, was a ferpent, called by the Phœnicians the "Good Genius." To this purpofe Eufebius obferves, that "the ferpent in the middle of a circle, which it touches in the two oppofite points of its circumference, indicates the Good Genius." For this object they chofe a particular fort of ferpent, of which Herodotus (l. ii.) gives the following defcription. "There are found, in the environs of Thebes, facred ferpents which are not venomous. They have two horns on the top of the head. When they die, they are buried in the temple of Jupiter. The name of Cneph, or Good Genius, was beftowed on them, as well as on the divinity they reprefented; and the veneration of the people extended no farther than to the image. The temple of Cneph may be regarded as the moft ancient in the country; and its exiftence has been alleged, in connection with thofe of Phtha and Neith, as an evidence that among the Egyptians the worfhip of the Creator, which was one of the dogmas of their religion, preceded every other. Cneph was fometimes reprefented in the fhape of a man of a dark-blue complexion, holding a girdle and a fceptre, with a royal plume on his head, and thrufting forth an egg out of his mouth, whence another God proceeded whom they named Phtha, denominated by the Greeks Vulcan. Thefe hieroglyphics have been thus explained; the intelligent being denoted by them is hidden and invifible, the giver of life, and the univerfal fovereign; and his being moved in an intellectual fpiritual manner, is fignified by the feathers on his head, and the egg, proceeding from his mouth, is interpreted to be the world.

CNESTIS, in *Botany*, (Κνηστις, Gr. from Κναω, or Κνεω, fcalpo; fo called on account of the prickly capfules which wound the fkin when rubbed againft them.) Willd. 911. Juff. 374. Vent. 3. 452. (Gratelier; Lam. Encyc.) Clafs and order, *decandria pentagynia*. Nat. Ord. *Terebintaceæ*, Juff. Vent.

Gen. Ch. *Cal.* deeply five-cleft; fegments oval or oblong, villous on the outfide, coloured within, caducous. *Cor.* Petals five, inferted into the receptacle, fometimes fhorter, fometimes longer than the calyx, alternating with its divifions. *Stam.* Filaments ten, attached to the receptacle, a little longer than the petals; anthers round, didymous. *Pift.* Germs five, fuperior, egg-fhaped, very villous; ftyle fhort; ftigma truncated, obfcurely two-lobed. *Peric.* Capfules five, diftinct, one or more frequently abortive, narrowed towards the bafe, villous, one-valved, opening longitudinally on one fide like thofe of fterculia or apocynum, a little curved. *Seeds* one in each capfule.

Eff. Ch. Calyx five-cleft. Petals five. Capfules five, one feeded.

Sp. 1. C. *glabra*, Lam. Encyc. 1. Ill. Pl. 387. Willd. 1. "Leaflets egg-fhaped, petioled, fmooth on both fides; racemes fafcicled, fhort, flender." A tree. *Leaves* fcattered; fituated near the ends of the branches, pinnated with an odd one. Common petioles from five to feven inches long, cylindrical, fmooth; leaflets from nine to fifteen, two inches long or more, entire, coriaceous, on very fhort petioles;

Flowers red or purple, small; racemes numerous, scarcely two inches long, cottony, lateral and terminal, corollas open, scarcely longer than the calyx. *Capsules* club-shaped, curved, six or seven lines long, russet, covered with an abundant prickly pubescence, which wounds the skin. A native of the isles of France and Bourbon. 2. C. *polyphylla.* Lam. 2. Willd. 2. "Leaflets ovate-oblong, somewhat villous, on very short petioles; racemes tomentous; capsules very obtuse." A tree, with the habit of the preceding. *Branches* somewhat cottony towards the summit. *Leaflets* about seventeen, sometimes slightly acuminate, nearly smooth above, nerved, and a little villous underneath. *Flowers* rather larger than those of the preceding species; racemes three inches long or more, a little fascicled, cottony, axillary, and terminal; petals narrowish, longer than the calyx. *Capsules* resembling those of the preceding, but quite obtuse. A native of Madagascar. 3. C. *corniculata*, Lam. 3. Mart. 3. (Spondioides pruriens; Smeathman, Herb.) "Leaflets oblong-acuminate; middle nerve villous; capsules oblong, acute, horn-shaped, tomentous, prurient." *Branches* woody, cylindrical, brown, slightly pubescent near the summit. *Leaves* more distant than in the preceding; leaflets about nine, an inch and a half long, entire. *Capsules* four or five, near an inch and a half long. Discovered by Smeathman, at Sierra-Leona. 4. C. *trifolia*, Lam. 4. Willd. 4. (Spondioides villosa; Smeathman, Herb.) "Leaves ternate; leaflets egg-shaped, acuminate, even-surfaced above, panicle terminal." *Branches* woody, cylindrical, cottony. *Leaves* alternate, sometimes almost opposite; petioles three inches long, cylindrical, cottony, leaflets entire, nerved and reticularly veined underneath, slightly tomentous; stipules small, setaceous or filiform. *Flowers* in a loose terminal panicle; peduncles cottony; bractes small, filiform. *Capsules* club-shaped, half an inch long, rather acute at their summit, curved, cottony. Found in Africa by Smeathman.

CNIDINIUM, in *Ancient Geography*, a strong place of Asia Minor, in Ionia, placed by Diodorus Siculus in the vicinity of the town of Ephesus.

CNIDUS, a town of Asia Minor, in Caria, in the province called Doris, at the extremity of a promontory, anciently denominated Triopium, now Cape Crio, having on the north the Ceramic, or Ceraunian bay, and on the south the Rhodian sea. This ancient city was much celebrated. Venus, its tutelary deity, was worshipped in this place; and hence she has been called the Cnidian Venus. Her statue, which was reckoned one of the most beautiful productions of Praxiteles, was placed here in a temple, which was open on all sides, so that the statue might be every where seen; and in whatever point of view it was examined, it excited equal admiration. No drapery veiled its charms; and its beauty was so singular and extraordinary, that it inflamed with a violent passion another Pygmalion, who, in the dark, endeavoured to animate a cold and insensible representation of a most fascinating woman, and there left traces of a mad profanation. (Pliny, H. N. l. xxxvi. c. 5.) Nicomedes, king of Bithynia, offered to pay the debts of this city, which were immense, in order to obtain this master-piece of art; but the Cnidians could not be prevailed upon to part with it. Pliny, who relates the fact, praises them for their refusal to surrender an object which immortalized their city, as well as their passion for the fine arts. In this place were other statues, which, destitute of the perfection and seducing graces of the Venus of Praxiteles, contributed no less to the public glory and prosperity, by the crowd of strangers who came hither to admire them. Heaps of ruins at this day occupy the place of one of the most splendid cities of ancient Greece; and the curious are prohibited from digging among them, in order to discover fragments of its ancient splendour. Independently of a taste for the arts, the Cnidians had also a genius for great enterprises. They had resolved to cut through the base of the large promontory which formed their domain, and to convert their peninsula into an island. Thus, their small craft would have avoided the long circuit of Cape Triopium, as well as the dangers of the tempestuous sea which breaks upon it; and their country, more insulated, would have been less exposed to attacks and surprises from the enemy. But an oracle suspended labours which were likely to conduce to the safety and prosperity of the state. It was found that the meaning of the two hexameter verses, pronounced by the Pythian at Delphi, signified that the inhabitants of Cnidus were to leave their isthmus such as it was; because, if Jupiter had willed it to be an island, he would have saved them the trouble of making it so; an absurd answer, calculated only to divert from the execution of grand projects, and worthy of personages who, on mysterious tripods, and in an obscure language, boasted of being the interpreters of the gods. The shores of Cnidus furnish now, as in former times, a great abundance of fishes, justifying the appellation of "Piscosam Cnidon," given it by Ovid. The wines of Cnidus were anciently very famous. Theophrastus (l. vii. c. 4.) speaks of Cnidian onions as of a particular species; they were very mild, and did not occasion tears.

CNIZOMENÆ, a people of Asia, placed by Diodorus Siculus in the vicinity of the Arabian gulf.

CNOPITZ, in *Geography*, a river of Carinthia, which runs into the Drave, about 6 miles S. W. of Saxenburg.

CNOSSUS, in *Ancient Geography*, a town situated on the northern coast of the island of Crete, towards the east, and at a small distance from the sea. According to Strabo (l. x.) it was formerly called Cœratus, or Ceretos, from the name of the river which watered it. This was famous for the residence and court of Minos, and as the abode of the most wealthy, as well as the most powerful and warlike, people of the whole island. Strabo says, that in extent it was 30 stadia. A small village, Cnossou, would serve to point out the scite of the ancient town, if it were not discoverable in the rubbish which covers it, and a great part of which has supplied materials for the building of modern Candia. The port of Cnossus was denominated Heraclæum.

CNOTHONDORF, in *Geography*, a town of Hungary, 18 miles W. of Tokay.

CNUPHIS, or CHNUMIS, in *Ancient Geography*, a city of Egypt, S. of Thebes, and on the fame fide of the river, fo called from a god of that name, worfhipped by the inhabitants. See CNEPH.

CO, a town of Egypt, and the capital of the Cynopolite nome.

COA, in *Botany*, *fcandens*, *fructu trigemino*, Plum. See HIPPOCRATEA *volubilis*.

COA, in *Ancient Geography*, a town of Arabia Felix, near the fea, and almoft oppofite to the ifland of Diofcorides, according to Ptolemy. It is mentioned in the books of Chronicles and Kings, on occafion of the horfes with which Solomon was fupplied by it.—Alfo, a river of Afia, which had its fource, according to Ptolemy, in Mount Imaus, and joining the river Suafte, difcharged itfelf into the Indus.

COA, in *Geography*, a river of Portugal, which runs into the Duero: 12 miles S. of St. Joanno de Pefqueira.

COACERVATUM VACUUM. See VACUUM.

COACH, a vehicle for commodious travelling, fufpended on leathers, and moved on wheels.

In England, and throughout Europe, the coaches are drawn by horfes, except in Spain, where they ufe mules. In a part of the Eaft, efpecially the dominions of the great Mogul, their coaches are drawn by oxen. In Denmark they fometimes yoke rein-deer in their coaches; though this is rather for curiofity than ufe.

The coachman is ordinarily placed on a feat raifed before the body of the coach. But the Spanifh policy has difplaced him in that country by a royal ordonnance; on occafion of the duke d'Olivares, who found that a very important fecret, whereon he had conferred in his coach, had been overheard, and revealed by his coachman; fince that time the place of the Spanifh coachman is the fame with that of the French ftage-coachman, and our poftillion, *viz.* on the firft horfe on the left.

If we derive the origin of the modern word *coach*, or *coche*, from *caroche*, or *caroffe*, and thefe from *caroccio*, we find that this term was known in the 14th century, and was probably invented not merely to defignate a military machine fo called, but was adopted from one already in ufe, fignifying a larger kind of car or waggon. Muratori, in his "Differtation on the Military Syftem of the rude ages in Italy," (vol. i. p. 360.) obferves, that the inventor of the caroche, introduced after the year 1000, was Eribert, archbifhop of Milan, in the 11th century, who directed that a ftandard of the following kind fhould precede his men as they marched to battle. A tall beam, like the maft of a fhip, fixed in a ftrong waggon, is raifed on high, bearing on the top a golden ball, with two very white ftreamers depending from it. In the middle, the holy crofs, painted with the image of our Saviour, with its arms widely fpread, overlooked the furrounding troops, fo that, whatever fhould be the event of the combat, they might be comforted with this fign. This is the undoubted origin of the military caroche, in imitation of which other more powerful cities afterwards formed them with a little variation, in order to ferve the purpofes of war. The caroche was ufed not only by the Milanefe, but alfo by the Bolognefe, Paduans, Veronefe, Brefcians, Cremonefe, Placentines, Parmefans, &c.; and it appears, that in the 13th century the ufe of the caroche was regarded as fingularly honourable, and of great avail in conquering the enemy. To lofe it was accounted an irreparable difgrace, as it was the higheft glory to take that of the adverfary. From Italy the ufe of thefe caroches paffed into Germany, Flanders, Hungary, and other countries, as Du Cange has remarked; but in the 14th century, when another mode of fighting was introduced, and they were found to be rather an incumbrance than an advantage, they ceafed to be employed. But to return from this digreffion to the hiftory of coaches, more properly fo called.

Some have thought, from the etymology of the word *coach*, to determine the country in which it was invented. But it would be much more eafy to afcertain the origin of the term, if we did but know by whom clofe-carriages were invented. Menage makes it Latin, and by a far-fetched derivation, traces it from "vehiculum." Junius derives it from οχεω, to carry. Wachter feeks its origin in the German word "kutten," to cover; and Lye in the Belgic "koetfen," to lie along, as it properly fignifies a couch or chair. The Italian derivation has been already mentioned. Others endeavour to prove, that the word *coach* is of Hungarian extraction, and that it had its rife from a village in the province of Weifelburg, which is at prefent called "kitfee," but was formerly known by the name of "kotfee," or "cotzi," and that this travelling machine was even there firft invented. However this be, it is certain that in the 16th century, or even at an earlier period, a kind of covered carriages was known, under the name of Hungarian carriages.

Beckmann, in his "Hiftory of Inventions" (vol. i. p. 111, &c.) has taken confiderable pains to prove, that covered carriages, under different forms and denominations, were ufed among the principal nations of antiquity. Accordingly, he fays, that the *arcera*, mentioned in the 12 tables, was a covered carriage, ufed by fick and infirm perfons. This was employed at an earlier period than the foft *lectica*, and difufed after this was introduced. A later invention was the *carpentum* (which fee); and at a ftill later period were introduced the *carrucæ*, concerning which fo little is known, that antiquaries are not certain, whether they had only one wheel, like our wheel-barrows, or, as is more probable, four wheels. (See CARRUCA.) In procefs of time covered carriages became more generally appendages of Roman pomp and luxury; but at length the fpirit of the feudal fyftem for fome time banifhed the ufe of them. The feudal lords, conceiving it to be of the greateft importance that their military vaffals fhould ferve them on horfe-back, were averfe from indulging them with elegant carriages, the prevalence of which would render them indolent, and unfit them for military fervice. Accordingly perfons of every rank, males and females, clergy and laity, rode upon horfes or mules, and fometimes upon fhe-affes. The minifter rode to court, the magiftrates of the imperial cities to council, even in the beginning of the 16th century, and great lords made their public entry on the moft folemn occafions on horfe-back. In the accounts of the papal ceremonies that occur, we find no mention of a ftate-coach, or body-coachman, but merely of ftate-horfes, or ftate-mules.

It was neceffary that a horfe for his holinefs fhould be of a grey colour, not mettlefome, but a quiet tractable nag; that a ftool with three fteps fhould be brought in order to affift him in mounting; and the emperor and kings, if prefent, held his ftirrup, and led his horfe, &c. Bifhops alfo made their public entrance on horfes or affes richly decorated. At the coronation of the emperor, the electors and principal officers of the empire were ordered to make their entrance on horfes, and to perform their fervice on horfeback. Moreover, it was formerly neceffary, that thofe who received an inveftiture fhould make their appearance on horfeback: the vaffal was obliged to ride with two attendants to his lord's court, where, having difmounted from his horfe, he received his fief. Covered carriages, however, were known in the principal ftates of Europe, in the 15th and 16th centuries; but they were at firft ufed by women of rank, and the men thought it difgraceful to ride in them. At this period, when

when the electors and princes did not chuse to be present at the meetings of the states, they excused themselves by informing the emperor that their health would not permit them to ride on horseback; and it was considered as unbecoming for them to ride like women. In the year 1544, when count Wolf of Barby was summoned by John Frederic, elector of Saxony, to go to Spires, to attend the convention of the states assembled there, he requested leave, on account of his ill state of health, to make use of a close carriage with four horses. The use of covered carriages was for a long time forbidden even to women. In the year 1545, the wife of a certain duke obtained from him, with great difficulty, permission to use a covered carriage in a journey to the baths, with this express stipulation, that her attendants should not have the same indulgence. It is nevertheless certain, that the emperors, kings, and princes, about the end of the 15th century, began to employ covered carriages on journies, and afterwards on public solemnities. Indeed, in the account of Don Ambrose Travasari's embassy, in 1433, we are informed that he made his entry into Mantua in a coach, *(un nobil cocchio tirato du spiritosi destrieri.)* In 1474, the emperor, Frederic III, visited Frankfort in a close carriage; and in the following year he came into the same city in a very magnificent covered carriage. In the description of the splendid tournament held by Joachim, elector of Brandenburg, at Ruppin in 1509, the electress appeared in a carriage all over gilt, accompanied by twelve other coaches, ornamented with crimson, and another of the duchess of Mecklenburg, which was hung with red satin. At the coronation of the emperor Maximilian, in 1562, the elector of Cologne had twelve carriages; and in 1594, when the margrave John Sigismund did homage at Warsaw, on account of Prussia, he had in his train thirty-six coaches with six horses each. Count Kevenhiller (cited by Beckmann,) describing the marriage of the emperor Ferdinand II. with a princess of Bavaria, says, "the bride rode with her sisters in a splendid carriage studded with gold; her maids of honour in carriages hung with black satin; and the rest of the ladies in neat leather carriages." The same author mentions the entrance of cardinal Deitrichstein into Vienna in 1611, and tells us that forty carriages went out to meet him. At the election of the emperor Matthias, the ambassador of Brandenburg had three coaches, which were constructed in a coarse manner, of four boards clumsily put together. When the consort of that emperor made her public entrance, on her marriage in 1611, she rode in a carriage covered with perfumed leather. Mary, infanta of Spain, consort of the preceding emperor, Ferdinand III., rode, in Carinthia, in 1631, in a glass carriage, in which no more than two persons could sit. The wedding-carriage of the first wife of the emperor Leopold, who was also a Spanish princess, cost, together with the harness, 38,000 florins. The coaches used by that emperor are thus described; "in the imperial coaches no great magnificence was to be seen; they were covered over with red cloth and black nails. The harness was black, and in the whole work there was no gold. The pannels were of glass, and on this account they were called the imperial glass coaches. On festivals the harness was ornamented with red silk fringes. The imperial coaches were distinguished only by their having leather traces; but the ladies in the imperial suite were obliged to be contented with carriages, the traces of which were made of ropes." At the magnificent court of duke Ernest Augustus, at Hanover, there were in the year 1681, fifty gilt coaches with six horses each. The first time that ambassadors appeared in coaches, in a public solemnity, was at the imperial commission held at Erfurth, in 1613, respecting the affair of Juliers.

In the history of France we find many proofs, that at Paris, in the 14th, 15th, and even the 16th centuries, the French monarchs rode commonly on horses, the servants of the court on mules, and the princesses, together with the principal ladies, sometimes on asses. In 1534, queen Eleonora and the princesses rode on white horses, during a sacred festival; and that private persons, *e. g.* physicians, used no carriages in the 15th century, has been inferred from the principal entrance to their public school, which was built in 1472, and which was so narrow, that a carriage could not pass through it, though it was one of the widest existing at that period. In Paris also, at all the palaces and public buildings, they had steps for mounting on horseback, such as those which the parliament caused to be erected in 1599. However, carriages appear to have been used at an early period in France. An ordinance of Philip the Fair, issued in 1294, for suppressing luxury, and in which the wives of the citizens are forbidden to use carriages (cars), is still preserved. Coaches or chariots are said to have been in use at the duke of Burgundy's court so early as 1445. (See Palaye's "Memoires sur l'Ancienne Chevalerie.") Under Francis I., or rather about 1550, somewhat later, there were at Paris, for the first time, only three coaches; one of which belonged to the queen, another to Diana de Poictiers, the mistress of two kings, Francis I. and Henry II., by the latter of whom she was created duchess of Valentinois, and the third to René de Laval, lord of Bois-Dauphin, who, being a corpulent unwieldy nobleman, was not able to ride on horseback. Others say, that the three first coaches belonged to Catherine de Medicis, Diana duchess of Angoulême, the natural daughter of Henry II., who died in 1619, and Christopher de Thou, first president of the parliament, the latter of whom was troubled with the gout; but his wife came to Paris on horseback. The other ministers of state soon followed his example. Henry IV. was assassinated in a coach, but he usually rode through the streets of Paris on horseback, and had only one coach for himself and his queen. We find, however, two coaches at the public solemnity on the arrival of the Spanish ambassador, Don Peter de Toledo, under the reign of this king. The coaches used at this time were not suspended by straps; they had a canopy supported by ornamented pillars; and the whole body was surrounded by curtains of stuff or leather, which might be drawn up. If Henry's coach had been furnished with glass, it is probable that he would not have been murdered. Bassompiere, in the reign of Louis XIII., is said to have been the first who projected a small coach with glasses: and the coach in which Louis XIV. made his public entrance about the middle of the 17th century, appears to have been a suspended carriage. The inventor of this very material improvement, or that of suspending the body of the carriage from elastic springs, cannot be ascertained. This is the only information relating to it that occurs, unless we allow that the first word of the following expression, "branlant et moult riche," which is applied to the carriage presented to the queen of France, in 1457, by the ambassador of Ladislaus V., king of Hungary and Bohemia, indicates that the carriage was suspended.

Twiss, in his "Travels through Spain and Portugal," says, that coaches were seen for the first time in Spain in the year 1546. To this purpose it is observed by Don Lorenzo Vander Hamin and Leon, in the first book of Don John of Austria's life, that Charles Pubest, a servant of Charles V. king and emperor, came in a coach or chariot, a thing rarely seen in these kingdoms. Whole cities ran out to stare at it, for at that time they only made use of carts drawn by oxen, and in them were seen the most considerable persons even of the court. Within a few years, about three score and ten, it was found necessary to prohibit coaches by royal proclamation. In Madrid, it is said, there are from four to five thousand gentlemen's carriages.

Towards the end of the thirteenth century, when Charles of Anjou made his entrance into Naples, the queen of Naples rode in a carriage, called by historians "caretta," the outside and inside of which were covered with sky-blue velvet, interspersed with golden lilies. From Naples the luxury of carriages spread over all Italy.

England lays claim to a very early use of coaches; but whatever may be the denomination under which they are mentioned, it is most probable that the ancient vehicles of this kind were merely cars, or a superior sort of waggons. From the life of St. Erkenwald, in sir William Dugdale's history of St. Paul, he appears to have used somewhat approaching to their construction, or a sort of chaise with wheels, in which he preached when he was old and infirm. This must have been as early, at least, as the year 675. Brooke, in his "Catalogue and Succession of Dukes, Earls, &c." says, that William de Ferrars, earl of Derby, died of a bruise occasioned by a fall from his coach in 1253. Mr. Dallaway, in his "Inquiry into the Origin of Heraldry," cites a manuscript register of the abbey of Gloucester, preserved in the archives of Queen's college, Oxford, which states the manner of conveying the body of Edward II., from Berkeley castle; "Iste tum abbas suo curru, honorificé ornato cum armis ejusdem ecclesiæ depictis, &c.;" and from which citation he infers that arms were painted at this early period on carriages and domestic furniture. From Stowe's survey of London, we learn, that the oldest carriages used by the ladies in England were known under the now obsolete name of "whirlicotes." When Richard II., towards the close of the 14th century, was obliged to fly from his rebellious subjects, he, and all his followers, were on horseback; but his mother, who was sick and weak, rode in a carriage. But this became afterwards unfashionable; for that monarch's queen, Anne, the daughter of the king of Bohemia, shewed the English ladies how gracefully and conveniently she could ride on a side-saddle; and, therefore, whirlicotes and chariots were disused, except at coronations and other public solemnities. In 1471, after the battle of Tewkesbury, which decided the fate of king Henry VI. and that of the house of Lancaster, when others fled in different directions, the queen was found in her chariot, almost dead with sorrow. (Hall's Chronicle.) In 1487, on occasion of a grand celebration of the feast of St. George, at Windsor, in the third year of king Henry VII., the queen and the king's mother rode in a chaise, covered with a rich cloth of gold, drawn by six coursers, harnessed with the same cloth of gold; and 21 ladies, habited in crimson velvet, rode on white palfreys. (Ashmole's Order of the Garter.) In the Northumberland household-book, the duke's chapel-stuff is ordered to be sent before by my lord's chariot; which use of it, about the year 1512, indicates that it bore little resemblance to the modern carriage of that name. In the procession of the funeral of Thomas Howard, duke of Norfolk, 1524, the body laid in a chariot was drawn by horses richly caparisoned; and before it, in its way to Thetford, where he was buried, went three coaches of friars. Holinshed says that queen Elizabeth used a chariot at a very early period (1558) of her reign. From these and many similar instances that might be cited, we may easily conjecture what kind of vehicle was the ancient coach. In every period of English history chairs and horse-litters, or hanging-waggons, occur, and they appear to have been the most easy and commodious machines for conveyance with which our ancestors were acquainted. Stowe, in his "Summarie of the English Chronicles," cited by Strutt, in his "Manners and Customs of the English," vol. ii., states, that, in 1555, Walter Ripon made a coach for the earl of Rutland, which was the first that was ever used in England; and, in 1564, the same Walter made the first hollow turning-coach, with pillars and arches, for her majesty; and again, in 1584, he made a chariot-throne, with four pillars behind, to bear a canopy with a crown imperial on the top, and before, two lower pillars, on which stood a lion and a dragon, the supporters of the arms of England. From Stowe's large chronicle we learn, that in the year 1564, Guylliam Boonen, a Dutchman, became the queen's coachman, and that he was the first that brought the use of coaches into England. Soon after, within the period of 20 years, they became common among the nobility and other persons of rank. About this time it is said long waggons, conveying passengers and commodities, were introduced. Anderson, in his "History of Commerce," says that coaches were first known in England about the year 1580, and that they were introduced from Germany by Fitz-Allen, earl of Arundel. He adds, from Stowe, that they were in general use by the nobility and gentry about the year 1605. But Mr. Strutt informs us, that it was a long time after the invention of coaches before a coach-box was added to the body; "for the coachman joineth a horse fixed to match a saddle-horse to the coach-tree; then he sitteth upon the saddle; and when there are four horses he drove those which went before him, guiding them with a rein." In the year 1598, when the English ambassador went to Scotland, he had a coach with him. The duke of Buckingham, the unworthy favourite of two kings, was the first person who rode with a coach and six horses, in 1619; in ridicule of which novel pomp, the earl of Northumberland put eight horses to his carriage.

Towards the end of the 16th century, John of Finland, on his return from England, among other articles of luxury, brought with him to Sweden the first coach. Before that period, the greatest lords in Sweden, when they travelled by land, carried their wives with them on horseback, and the princesses travelled in the same manner.

In Dâ Roches's "History of Denmark," there are two passages, in which coaches are mentioned as existing in that country in the time of Christian II. about the year 1515; but, perhaps, they merely mean the covered carts which are still used in Westphalia and its neighbourhood.

It appears that in the capital of Russia there were elegant coaches as early as the beginning of the 17th century. At Amsterdam coaches with wheels were prohibited in the year 1663, in order to save the expensive pavement of the streets, for coaches there, even in summer, are placed upon sledges as those at Petersburg are in winter. Many attempts have been made to suppress the use of coaches. The feudal nobility and vassals on the continent were forbidden the use of coaches, under pain of incurring the punishment of felony. In 1588, duke Julius of Brunswick published an order, prohibiting his vassals to ride in carriages; and in 1608, Philip II., duke of Pomerania-Stetten, reminded his vassals, that they ought not to make so much use of carriages as of horses. These prohibitions, however, have been of no avail; and coaches became common all over Germany.

Louis XIV. of France, made several sumptuary laws for restraining the excessive richness of coaches, prohibiting the use of gold, silver, &c. therein, but they have had the fate to be neglected.

Coaches may be divided into two kinds; those that have iron bows, or necks, and those that have not; both the one and the other have two principal parts, the body, and the train,

train, or carriage. The *body* is that part where the paffengers are difpofed; and the *carriage* is that which fuftains the body, and to which the wheels are faftened, that give motion to the whole machine.

There have been various contrivances among coach-makers to enable coaches, and other four-wheeled carriages, to turn fhorter than the common coaches, without the fore wheels touching the perch. The moft common and effective among thefe, is a contrivance called the *crane-neck*, a reprefentation of which is given in *Plate* XIII. *fig.* 1. of *Mechanics*. In the place of the common fingle perch or pole, which connects the two axletrees together, two iron perches, A, A, are fubftituted; they are firmly attached to a ftout piece of wood, B, by bolts and fcrews; this piece, which carries the two fprings, D, D, at its ends, has another, E, halved into it at right angles, that fupports, at its end, a third beam, F, parallel to the firft, the ufe of which is to hold iron braces, *b*, *b*, for the fprings, and to ftrengthen the perches A, A, which are connected to it by fcrew-bolts at the place where they crofs each other. The perch-bolt, *a*, round which the fore-axle moves as a centre, when the coach is in the act of turning, paffes through the interfection of the pieces B and E, and alfo through the axletree G. H is an iron circle concentric with the perch-bolt, firmly fixed to the axletree, on which the ends of the pieces B and E reft, fo as to guard againft the perch-bolt being broken or bent by any fudden jerk when the carriage is turning. The remainder of the carriage is made in the common way, and the improvement confifts in bending the two perches, A, A, upwards, fo that the fore wheels can turn under them, and might be made to turn quite round, if neceffary.

Fig. 2, reprefents a contrivance of Mr. Jacob, of Greek-ftreet, Soho-fquare, for the fame purpofe. A is the perch, as in a common coach, B the piece carrying the fprings, and F the piece fupporting their braces, bolted acrofs the perch at right angles; *a* is the perch-bolt, which does not pafs through the axletree itfelf, but through a piece of wood, G, projecting perpendicularly from the middle of the axletree, about half the diameter of the fore-wheels, and is firmly fixed to it by bolts and ftraps of iron; the axletree, H, is ftraight on the upper fide, and has a ftraight edge of iron fcrewed on the top of it, on which the end of the perch, A, is fupported; the under fide of the perch is alfo faced with iron, where it lies upon the axletree. It is evident, from the drawing, that by removing the perch-bolt to a diftance from the axletree, by means of the piece G, the axletree may be turned round much nearer into a line with the perch, without either of the wheels touching it, than it could do, if the perch-bolt went through the middle of it, as in the common way. By this contrivance, though it does not poffefs all the advantages of the crane neck, coaches may be made to turn much fhorter than the common ones, without any increafe of expence in their conftruction.

Coaches are diftinguifhed, with regard to their ftructure, into *coaches*, properly fo called, *chariots*, *calafhes*, and *berlins*. With regard to the circumftances of their ufe, &c. we diftinguifh *ftage-coaches*, *hackney-coaches*, &c.

Chariot, or *Half*-Coach, is a kind of coach that has only a feat behind, with a ftool, at moft, before. When thefe are very gay, richly garnifhed, and have five glaffes, they are called Calashes.

By 43 Geo. III. c 161. repealing former acts, the following duties are impofed on carriages, to take place from April 5, 1804, and they are levied under the provifions of the 43 Geo. III. c. 99, and by 45 Geo. III c. 15, &c. *viz.* for one carriage with four wheels, the annual fum of 11*l.*; for two fuch carriages, 24*l.* 4*s.*; for three, 39*l.* 12*s.*; for four, 55*l.*; for five, 71*l.* 10*s.*; for fix, 89*l.* 2*s.*; for feven, 107*l.* 16*s.*; for eight, 127*l.* 3*s.*; for nine 148*l.* 10*s.*; and an additional 16*l.* 10*s.* for every other carriage: and for every additional body, fucceffively ufed on the fame carriage or number of wheels, the further fum of 15*s.* 6*d.*:—For every carriage with lefs than four wheels (tax-carts excepted) drawn by one horfe, 5*l.* 15*s.* 6*d.*; and drawn by two or more horfes, 8*l.* 1*s.* 8¼*d.*; and for every additional body, fucceffively ufed on the fame carriage or number of wheels, the further fum of 2*l.* 15*s.*:—For every carriage, kept for the purpofe of being let to hire, for any period not exceeding 28 days, fo that the ftamp-office duty, payable by law on horfes let to hire, fhall be duly paid and fatisfied on every fuch letting by a licenfed perfon, if fuch carriage have four wheels, as above; if it have lefs than four wheels, the refpective fums above mentioned in the cafe of the fame carriages:—all which duties fhall be refpectively paid by the perfon keeping the fame:—For every carriage kept for the purpofe of being let to hire, for any period of time lefs than one year, and in fuch manner, that the faid ftamp-office duty fhall not be payable to fuch letting by any fuch licenfed perfon, if the carriage fhall have four wheels, the annual fum above ftated; and if fuch carriage have lefs than four wheels, the refpective fums above mentioned. Poft chaifes are chargeable with eight guineas each. By 43 Geo. III. c. 161, the following new duties are to be paid by coach-makers, and on carriages built for fale, in lieu of the duties thereby repealed; and alfo the new duties on perfons vending fuch carriages by auction or commiffion: *viz.* by every perfon who fhall carry on the trade of a coach-maker, &c. the annual duty of 5*s.*; by every fuch coach-maker for every carriage with four wheels, made for fale, 1*l.*, and for every fuch carriage with two wheels, 10*s.*:—By every perfon who fhall fell any carriage chargeable with duty by this act, by way of auction or commiffion, the annual duty of 5*s.*; by every fuch perfon for every fuch carriage with four wheels, which he fhall fell by auction or on commiffion, 1*l*, and for every fuch carriage with two wheels, fo fold, 10*s.* Perfons who have kept any carriages in the year ending on the days appointed for the commencement of the duties in 1804, are to return lifts to the affeffors; and perfons beginning or ceafing to keep carriages, or to carry on the trade of coach-makers, are to give notice of the fame. Coach-makers are required to keep accounts of carriages built or fold by auction or on commiffion. The affeffors, &c. to whom fuch accounts are delivered, fhall certify the fame to commiffioners.

The number of coaches made in England in the year 1793, is faid to have amounted to 40,000, more than half of which were exported. By the yearly accounts of the net produce of the permanent taxes, it appears that the duty on four-wheeled carriages (exclufive of hackney coaches) amounted in the year 1803 to 184,389*l.* 5*s.* 7½*d.* and in 1804, to 172,013*l.* 5*s.* 5½*d.*; and the duty on two wheeled carriages, to 90,090*l.* 2*s.* 7¾*d.* and 119,866*l.* 11*s.* 5¼*d.* refpectively: and the amount of the duties on both forts of carriages was 260,589*l.* 13*s.* 9½*d.* in 1805, 260,088*l.* 4*s.* 7½*d.* in 1806, and 302,349*l.* 3*s.* 2*d.* in 1807 refpectively. The duties upon hackney coaches and chairs amounted in 1806 to 24,325*l.* 2*s.* and in 1807 to 25,857*l.*

Coaches, *Hackney*, thofe expofed to hire in the ftreets of London, and fome other great cities, at rates fixed by authority.

Thefe firft began to ply in the ftreets of London, or rather waited at inns, in 1625, and were only twenty in number; but they were fo much increafed in 1635, that king Charles iffued an order of council for reftraining them. In 1637, 1637, he allowed fifty hackney-coachmen, each of whom might keep twelve horses. In 1652 their number was limited to two hundred, and in 1654 extended to three hundred, for which 600 horses were employed. In 1661 four hundred were licensed at 5*l.* annually for each. In 1694 seven hundred were allowed, and taxed by the 5 and 6 W. and M. at 4*l.* per annum each.

By 9 Anne, cap. 23, the king may appoint commissioners, not exceeding five in number, for regulating hackney-coaches within the bills of mortality; and by this statute eight hundred hackney-coaches were allowed in London and Westminster; but by 11 Geo. III. cap. 24, the number was increased to one thousand; and by 42 Geo. III. c. 78. one hundred more was added, which are to be licensed by the commissioners, and pay a duty of 5*s.* per week (9 Anne. c. 23.) and an additional duty of 5*s.* per week (24 Geo. III. sess. 2. c. 27.) for each licence to the crown, to be paid monthly: and if any person drive or let to hire a hackney-coach without licence, he shall forfeit 5*l.* The commissioners may appoint inspectors to see that licensed persons provide safe and clean coaches and sufficient horses, and suspend the licence of any person whose coach or horses shall be found defective (39 and 40 Geo. III. §. 4.); nor shall any horse be used with any hackney-coach under the height of 14 hands (9 Anne. c. 23.). By the same statute every coach is to have a distinct mark or number on both sides, which is not to be altered under penalty of 5*l.* No unlicensed coaches shall ply at funerals for hire, or without having a number fixed on the fore-standard, shewing it to be licensed, on pain of 5*l.* 1 Geo. c. 57. 24. Geo. III. sess. 2. c. 27. By 1 Geo. c. 57. refusing any person to take the number of the coach, or giving a wrong number, incurs the forfeiture of a sum not exceeding 40*s.* By 11 Geo. III. c. 28. every hackney-coach is to be provided with checque-strings, and plying without them incurs a penalty of 5*s.*; and by 1 Geo. c. 57. drivers of hackney-coaches are to give way to persons of quality and gentlemen's coaches, under penalty of 10*s.*

By 39 and 40 G. III. c. 47. the fares on hackney coaches allowed by 26 G. III. c. 72. are repealed, and the following fares are to be taken in lieu thereof: namely, between six in the morning and twelve at night for every distance not exceeding one mile 1*s.* and for every further distance not exceeding half a mile 6*d.* and increasing 6*d.* for every half mile such coach shall go farther. s. 1.

And as to time, for every coach kept in waiting between six in the morning and twelve at night, for not exceeding 40 minutes 1*s.* and for any further time not exceeding 20 minutes 6*d.* and so on during the whole time such coach shall be engaged, computing at the rate of 6*d.* for every 20 minutes.

And for every coach hired where there is a regular continuation of carriage-way pavement, or at any stand beyond such continuation, and taken to, and discharged at any place from which the same cannot be driven to the nearest continuation of such carriage-way pavement, or such stand, before sun-set, (estimating the rate of driving at five miles an hour,) then one half part of the fare hereby allowed for such distance as such coach can be so driven towards such nearest pavement before sun-set, so as no fraction of any sum less than 6*d.* shall be payable by reason of such half rate; and the full rate hereby allowed shall be paid for such distance as shall remain for such coach to be driven at the rate aforesaid to such pavement after sun-set, or where such coach shall have been hired at any standing beyond such pavement, then to such standing or to the nearest pavement, at the option of the person discharging such coach.

And every coach hired for a day not exceeding 12 hours, and to end before 12 o'clock at night, and the distance not to exceed 20 miles, shall be paid 18*s.* for such day's work, and for any further time or distance or if after 12 at night, such further rate for such time or distance as is allowed for any further time or distance of the like nature by this act: And also if any such coach shall be taken to and discharged at any place exceeding one mile from where there is a regular carriage-way pavement, so as that such coach cannot be driven to such pavement within such 12 hours, or before 12 at night; or where the distance where such coach shall be discharged, added to the distance such coach shall have been driven, shall in the whole exceed 20 miles, then such further additional rate as is herein allowed for any further time or distance of the like nature.

And for every such coach which shall be hired or kept in waiting after twelve at night or before six in the morning, or shall be discharged at any such time and place that it cannot be driven to some regular carriage-way pavement before twelve at night, an additional fare for such time or distance as aforesaid, over and above the rate before mentioned, of 6*d.* upon every 1*s.* but so that such additional rate shall not be taken for any such coach hired between ten and twelve o'clock at night, unless the rate, according to the time for which such coach shall be kept, or the distance such coach shall be taken, shall according to the rates aforesaid amount to 2*s.* or upwards, although such coach shall not be discharged till after twelve at night.

And when the average price of oats computed according to 31 G. III. c. 30. shall exceed 25*s.* per quarter, the commissioners for licensing hackney coaches may allow additional fares to be taken, *viz.* 6*d.* on every 2*s.* fare: 1*s.* on every 4*s.* fare, and so 6*d.* additional on every additional 2*s.* provided the coach goes or is kept to the full amount of the fare; and such additional rates may be continued till 30 days after oats are reduced to one guinea per quarter. s. 2, 3.

Every licensed coachman, plying for hire, within the cities of London and Westminster, or the suburbs thereof, or elsewhere within the bills of mortality, shall be obliged and compellable, on every day of the week, at seasonable times, to go any where within the distance of ten miles from either of the said cities. 7 G. III. c. 44. s. 12. 12 G. III. c. 49, s. 1.

No person who shall regularly use such hackney coach as a stage coach to and from any of the towns or places in the neighbourhood of London or Westminster, shall be obliged to carry any fare out of the ordinary course of his stage work or duty; provided that he do, by painting in legible characters, on the door of such coach, or on a board to be affixed on such door, plainly denote and distinguish the same to be a stage coach to and from any such town or place. 12 G. III. c. 49. s. 2.

If any hackney coachman shall refuse to go at, or exact more for his hire, than according to the above act, or bye-laws; he shall forfeit a sum not exceeding 3*l.* nor under 10*s.* 1 G. st. 2. c. 57. s. 2.

And every hackney coachman where coaches are standing, shall be compellable to go with any person when desired, and on refusal, (unless he prove being hired) shall be liable to the like penalties as persons refusing to carry for hire, by any law now in being. 39 and 40. G. III. c. 48. s. 5.

Hackney coachmen exacting more than their fare, shall be liable to the penalties, and their fares shall be recoverable, as under former acts. s. 11.

And if any person who shall drive a coach, or carry a chair for hire, acting under a person licensed, shall be guilty of misbehaviour, by demanding more than his fare, or giving abusive

abusive language, or other rude behaviour; he shall, on conviction on oath, forfeit not exceeding 20 s. to the poor; and if he shall not be able, or refuse to pay, he shall be committed to Bridewell or some other house of correction, to be kept to hard labour for seven days, and receive the public correction of the house before he be discharged. 9 An. c. 23. s. 44.

And on misbehaviour of a coachman or chairman by abusive language, or otherwise, the commissioners may revoke his licence, or inflicton him a penalty, not exceeding 3 l. to the poor; and on non-payment, he shall be committed to Bridewell or some other house of correction, to be kept to hard labour for 30 days. 9 An. c. 23. s. 49. 7 Geo. III. c. 44. s. 16.

If any person shall refuse to pay, or shall deface any coach or chair, any justice may grant his warrant to bring him before him; and on proof upon oath may award satisfaction to the party, and on refusal to pay, may bind him over to the next sessions, who may determine the same. 9 An. c. 23. s. 22.

And if any hackney coachman or his renter, shall be in arrear for any rent made payable by his licence for any longer time than is expressed therein, the said commissioners may revoke such licence, and levy the money upon the goods of either the owner or renter, in like manner and form as by any law now in being with respect to the owner. 26 G. III. c. 72. s. 3.

The rents and penalties to be levied by distress, by warrant of three commissioners; which distress shall be sold in ten days, returning the overplus, charges of the distress and of the warrant being first deducted (if on seven days' notice they pay not the fine without such warrant); and in default of distress, to be imprisoned till paid; and if any rent shall be unpaid for 14 days, the commissioners may withdraw the licence. 9 An. c. 23. s. 12.

And moreover, the breach of the bye-laws, and of these rules and orders, may be punished by any justice of the peace, mayor, bailiff, or other magistrate, where the offence shall be committed, in like manner as by the commissioners. 9 An. c. 23. s. 17. 1 G. st. 2. c. 57. s. 7. 4 G. III. c. 36. 7 G. III. c. 44. s. 19. 10 G. III. c. 44. s. 7.

And every licensed person who shall neglect or refuse (being duly summoned for that purpose) to appear by himself or his renter, shall forfeit 10 s. to be recovered as the other penalties; and if such licensed person shall neglect or refuse to appear, together with his renter, upon the third summons, the complaint may be heard and determined in his absence. 10 G. III. c. 44. s. 6.

And if any owner of a licensed hackney coach, shall refuse or neglect to appear with his driver before the commissioners upon the third summons left at his usual place of abode, the said commissioners may revoke such licence, and licence another person in his room. 24 G. III. sess. 2. c. 27. s. 37.

And all penalties levied by any justice, mayor, bailiff, or other magistrate, shall by them be transmitted to the receiver general of the duties on hackney coaches and chairs, and they shall also transmit a certificate thereof to the commissioners, within ten days after levying such penalty, on pain of 10 l. half to the king and half to him that shall sue. 10 G. 3. c. 44. s. 8.

Hackney coaches were first established at Edinburgh in 1673; and carriages of this kind have been introduced within some years, in several principal cities and towns of England. At Paris, and in some other places in the continent, they are known, by the name of "fiacres." This appellation is said by Beckmann to have originated in France, about the year 1650, when one Nicholas Sauvage first thought of keeping horses and carriages for hire; and as he lived in a house called the "hôtel S. Fiacre," the coaches, coachmen, and proprietor were called "fiacres." A particular kind of hackney carriage is peculiar to the Parisians; it is denominated "brouette," or "roulette," and sometimes by way of derision, "vinaigrette;" and was invented by a person of the name of Dupin; the body is almost like that of our sedans, but rolls upon two wheels, and is dragged forwards by men. Carriages of this kind came into common use in 1671, but they were employed only by the common people. The number of all the coaches at Paris is computed (says Beckmann) at about 15,000; and the author of the "Tableau de Paris," reckons the number of the hackney coaches to amount to 1800, and asserts that more than 100 foot passengers lose their lives by them every year. Fiacres were introduced at Warsaw, for the first time, in 1778. In Copenhagen there are 100 hackney coaches. In Madrid there are from 4 to 5,000 gentlemen's carriages; in Vienna 3000, and 200 hackney coaches.

COACHES, *Stage*, are those appointed for the conveyance of travellers from one city or town to another; and these, as well as other coaches, chaises, &c. with four wheels, pay an annual tax of 8 l. 8 s.

Persons keeping stage-coaches for the purpose of conveying passengers by hire, shall take out a licence at 5 s. annually, and renew it on pain of forfeiting 10 l. 25 Geo. III. c. 51. By 30 Geo. III. c. 36. it is enacted, that the drivers of stage-coaches, drawn by three or more horses, are not to admit more than one outside passenger on the box, and four on the roof, under a penalty of 5 s. for every person above the limited number, to be paid to the toll-taker at every turnpike gate through which such carriage shall pass; the proprietor's name shall be put on the carriage; and if the coachman shall suffer any person to drive the same, without the consent of the inside passengers, or quit the box without reasonable occasion, or for a longer time than such occasion may require; or shall, by furiously driving, negligence, or misconduct, overturn the carriage, or endanger the persons or property of the passengers, or of the owner of such carriage, he shall for every such offence forfeit not exceeding 5 l. nor less than 40 s.; and if the guard fire without cause, he shall forfeit for every such offence 20 s. If the driver cannot be found, the proprietor of such carriage shall be liable to the penalty laid upon the driver. The penalties are to be applied, half to the informer, and half to the surveyor of the highways in the place where the offence is committed, for the repair of the highways. See POST-*horses*.

COACH, in *Sea Language*, denotes a chamber or apartment near the stern, in a ship of war.

COADJUTOR, *Fellow-helper*, is properly used for a prelate joined to another, to assist him in the discharge of the functions of his prelature; and even, in virtue thereof, to succeed him.

The coadjutor has the same privileges with the bishop himself. Coadjutors were formerly appointed by kings, for archbishops and bishops grown old, or absent, and not able to superintend their dioceses. But the right of appointing coadjutors, in Romish countries, is now reserved to the pope alone.

Coadjutors are also called bishops *in partibus infidelium*; because it is necessary the coadjutor of a bishop should be a bishop himself; without which he cannot discharge the office.

The use of coadjutors in the church, is borrowed from the Roman empire. Symmachus speaks of assistants, or coadjutors, given to magistrates, and calls them *adjutores publici officii.* See SUFFRAGAN.

The popes formerly made a shameful abuse of the coadjutories;

jutories;

jutories; some they granted to children, and young people, with this clause, *donec ingressus fuerit; till they were capable of entering upon the administration of the office.* Others they granted to persons not in orders, with this clause, *donec accesserit;* and others to persons at a great distance, with this clause, *cum regressus;* but the council of Trent tied down the pope's hands, by adding abundance of restrictions on the article of coadjutors.

In nunneries they have coädjutrixes, who are religious, nominated to succeed the abbess, under pretence of aiding her in the discharge of her office.

COADUNATÆ, in *Botany*, the 12th of the natural orders of Linnæus in the Philosophia Botanica, and the 52d of the Posthumous Prælections. In the former it contains the following genera; annona, liriodendrum, magnolia, uvaria, michelia, and thea. In the latter xylopia is added, and thea removed to columniferæ. Linnæus has left no explanation of this order.

COAGMENTATION, is used, among chemists, for the act of melting down a matter, by casting in certain powders, and afterwards reducing the whole into a concrete or solid.

COAGUILLA, or NEW ESTREMADURA, in *Geography*, a province of New Leon, part of the Spanish dominions in North America; the bounds of which are extended by Alcedo to the river Medina, and the extent of which is computed at 200 leagues from N. to S. and 160 from N.W. to N.E. The capital is Monclova, in lat. 27° 30′. This province is a desert waste, scarcely peopled, except by some Missions; and its mineral treasures, if any exist, have not been explored.

COAGULATION, in *Chemistry.* A liquid is said to coagulate when it becomes solid, or nearly so, without assuming a regular crystallized form, and without the loss of the more fluid part by evaporation, or by any other method. The solidification of the white of egg by heat, and the spontaneous stiffening of blood when drawn from the living vein, are familiar examples of coagulation. We are perfectly ignorant both of the cause of coagulation in these cases, and of the nature of the change that takes place in them.

In many cases a thickening, which is also termed coagulation, is produced in liquid solutions, by certain additions, which exercise a well-defined chemical action. In this case coagulation is synonymous with incipient and copious precipitation, where the relative bulk of fluid is small; as, for example, where milk is coagulated by rennet, which produces a separation between the curd and whey; but before the separation is complete the whole mass stiffens, or coagulates. This term is also applied to a sudden and copious production of crystals, so minute or irregular, as hardly to assume to the naked eye the crystalline form, as when strong sulphuric acid is poured into a concentrated alkaline solution, which immediately converts the whole into a confused mass of sulphat of potash.

COAGULUM, the *coagulum* of the Latins, the πιτυα, and the ταμισος of the Greeks, are the same with what in English we call rennet. See RENNET.

COAITA, in *Zoology*. See SIMIA *paniscus*.

COAK. See COKE.

COAKS, in *Ship-Building*, denote oblong ridges left on the surface of different pieces of made-masts, by cutting away the wood round them, the intermediate part being called the plain.

COAKING, is the uniting of two or more pieces together in the middle, by small tubular pieces, formed from the solid of one piece, and sunk exactly the same in the other, the butts of which prevent the pieces from drawing asunder length-ways. There are different methods of coaking, such as the following:—*Coak and plain*, when a coak is formed, and a plain surface follows between that and the next:—*Running coaks*, which are coaks continued through the whole length along the middle, but answering the above purpose, as the butts of each coak come one-third of their breadth within and without each other alternately:—*Chain-coaks*, which are formed one at the end of the other, on the opposite sides of the middle line. See TABLING.

COAKING, or *Bushing*, in *Block-making*, denotes letting through the middle of a sheave a cylindrical piece of metal, with a hole through its centre, to admit the pin or axis on which the sheave turns; on each side of the sheave a plate is let in, having three or four corresponding holes in each, for rivets to go through, to secure and strengthen the whole. The entrance of the holes in the plates is enlarged, that the heads of the rivets and points, when clenched, may have a smooth surface. When there is only one plate, the rivets have broad heads; the holes in the sheave are made accordingly, and the points are clenched on the plate. The cylinder and one plate are cast in one piece.

COAKING, *plank*, is letting in narrow pieces of lignum-vitæ, transversely to each other, one on each side of the sheave; which has likewise a small circular brass plate let in on each side, and riveted through, as others.

COAL, in *Mineralogy*. The word coal has been derived by some writers from the Hebrew, and by others from the Greek or Latin, but whatever may be its origin, it is deserving of remark that the same sound for the same object is used in the Anglo-Saxon, the Teutonic, the Dutch, the Danish, and the Islandic languages. Coals are found in several parts of the continent of Europe, but the principal mines are in this country. They have been discovered and wrought in Newfoundland, Cape Breton, Canada, and in some of the provinces of New England. China abounds in them, and they are well known in Tartary, and in the island of Madagascar.

History of Coal as an Article of Commerce.

Coals are first mentioned as fuel for artificers by Theophrastus, who describes them as earthy substances that burn like wood-coals, and are used by the smiths. The ancient Britons had a primitive name for this fossil, and Pennant says, "that a flint axe, the instrument of the aborigines of our island, was discovered in a certain vein of coal in Monmouthshire, and in such a situation as to render it very accessible to the inexperienced natives, who in early times were incapable of pursuing the seams to any great depths."

Although coals are so abundant in many of the above named places, yet as there are no beds found in the whole extent of Italy, the great line of this fuel seems to sweep round the globe, from the north-east to the south-west, visiting Brabant and France, and avoiding Italy. The strongest argument adduced by those who contend that the Romans, while in possession of this island, were ignorant of the use of coal, is, that there is no name for it in the Latin language, the word *carbo* being always used for charcoal. Cæsar takes no notice of coal in his description of this island; yet there is good evidence to believe that the Romans brought it into use. In the West Riding of Yorkshire are many beds of cinders, heaped up in the fields, in one of which a number of Roman coins were found some years ago.

From Horsely it appears, that there was a colliery at Benwell, about four miles west of Newcastle-upon-Tyne, supposed to have been actually worked by the Romans, and it is evident from Whitaker, that coals were used as fuel in this country by the Saxons. No mention is made of this fossil during the Danish usurpation, nor for many years after the Norman conquest.

The firſt charter for the licence of digging coals, was granted by king Henry III., in the year 1239; it was there denominated ſea-coal; and, in 1281, Newcaſtle was famous for its great trade in this article, but in 1306, the uſe of ſea-coal was prohibited in London, from its ſuppoſed tendency to corrupt the air. Shortly after this, it was the common fuel at the king's palace in London, and, in 1325, a trade was opened between France and England, in which corn was imported, and coals exported. In 1379, a duty of ſixpence per ton was impoſed upon ſhips coming from Newcaſtle with coals. At this period, the inhabitants of the county of Durham had obtained no privilege to load or unload coals on the ſouth ſide of the Tyne; but, in 1384, Richard II., on account of his devotion to Cuthbert, the tutelary ſaint of Durham, granted them licence to export the produce of their mines, without paying any duties to the corporation of Newcaſtle. In the year 1421, it was enacted, that the keels or lighters carrying coals to the ſhips ſhould meaſure exactly twenty chaldrons, to prevent frauds in the duties payable to the king.

Æneas Sylvius, afterwards pope Pius II., viſited this iſland, about the middle of the 15th century, and he remarked, that the poor of Scotland received for alms pieces of ſtone, which they burnt in place of wood, of which at that time the country was deſtitute. About the beginning of the 16th century, the beſt coals were ſold in London at the rate of 4*s.* 1*d.* per chaldron, and at Newcaſtle for about 2*s.* 6*d.*; and in 1563, an act was paſſed in Scotland to prevent the exportation of coals, which had occaſioned a great dearth of fuel in that country. Queen Elizabeth, in the year 1582, obtained a leaſe of a great part of the mines of Durham, for ninety-three years, at the annual rent of 90*l.*, which occaſioned an advance in the price of coals; it was afterwards aſſigned to Thomas Sutton, the founder of the Charter-Houſe in London, who aſſigned it to the corporation of Newcaſtle, for the ſum of 12,000*l.*; and the price of coals was immediately advanced to ſeven ſhillings and eight ſhillings per chaldron. Notwithſtanding the ſeveral advances upon this article, when queen Elizabeth demanded the arrears of two-pence per chaldron, which had been granted to Henry V., but the payment of which had been neglected by the corporation, they petitioned for a remiſſion of the debt on account of their inability; this was granted, and alſo a charter to incorporate a new company, called hoſtmen or coal-engroſſers, for ſelling all coals to the ſhipping; in conſequence of which the corporation impoſed one ſhilling per chaldron additional upon this article. At this period the lord mayor of London complained to the lord-treaſurer, Burleigh, that the free-hoſts in Newcaſtle, to whom the grand-leaſe had been aſſigned, for the uſe of the town, had transferred their right to a few perſons, who engroſſed all the other collieries, and he requeſted that the collieries might be free, and that the price of coals ſhould not exceed ſeven ſhillings per chaldron.

It appears, by an order of the hoſtman's company, dated A.D. 1600, that tram-waggons and waggon-ways had not then been invented, but that the coals were at that time brought down from the pits in wains, holding eight bolls each (all of them meaſured and marked), to the ſtaiths by the ſide of the river. About this period, an engine for drawing the water out of the coal mines was invented in Scotland, by a predeceſſor of the firſt earl of Balcarras, who obtained from James VI. a patent for 21 years. This improvement was not, till ſome time after, adopted in the neighbourhood of Newcaſtle.

In a petition of grievances, preſented by the houſe of commons to king James, in 1610, a complaint occurs of a late impoſition of one ſhilling per chaldron on ſea-coals, riſing in Blyth and Sunderland, not by virtue of any contract or grant, as on the coals of Newcaſtle, but under the mere pretext, aſſumed by the contractors, of his majeſty's royal prerogative. This petition diſplayed ſo ſtrongly the rapacity of that body of men, and the diſtreſs occaſioned by it to the inhabitants of London, that the prayer of the petition was immediately complied with. It was during the ſame reign, that an information was exhibited in the ſtar-chamber, by the attorney-general, againſt the mayor and burgeſſes of Newcaſtle, by the name of hoſtmen, for that they, having the preemption of coals for the inheritors in Northumberland, and the county of Durham, by their charter of the 42d of Elizabeth, forced ſhips to take bad coals, amongſt which was a quantity of ſlate; in conſequence of this they were all fined, ſome of them in penalties of one hundred pounds each, and committed to the Fleet priſon; and the decree was ordered to be read in the open market in Newcaſtle, two ſeveral market days.

In 1615, there were employed in the coal trade of Newcaſtle 400 ſail of ſhips, one-half of which ſupplied London, the remainder the other part of the kingdom; the French too are repreſented as trading to Newcaſtle at this time for coal, in fleets of 50 ſail at once, ſerving the ports of Picardy, Normandy, Bretagne, and as far as Rochelle and Bourdeaux, while the ſhips of Bremen, Embden, Holland, and Zealand, were ſupplying the inhabitants of Flanders.

In 1622, an order was iſſued by the hoſtmen, againſt the ſecret and diſorderly loading of coals, but not until they had received ſeveral precepts from the king and privy-council, concerning this abuſe. They were ſummoned to anſwer again, by proceſs from the exchequer chamber, againſt the governor, ſtewards, and ſome others of the company, for the above default; and as we are not informed of the reſult of this proceeding, we may conclude it did not terminate in their favour. Soon after this, David Ramſay, a great projector, obtained an excluſive charter to raiſe water from low mines and coal pits, by a method entirely original. In the year 1630, the king let to farm an impoſt on coals of 5*s.* per chaldron, for thoſe tranſported out of England, Wales, and Berwick-upon-Tweed, to any part beyond the ſeas, except Guernſey, Jerſey, and the Iſle of Man; of 1*s.* 8*d.* over and above the 5*s.* on thoſe to be exported, as above, by any Engliſhman; and alſo of 3*s.* 4*d.* for every chaldron to be exported except for Ireland and Scotland. In 1631, an information was again made in the ſtar-chamber, by Heath, attorney-general, againſt the hoſtmen of Newcaſtle, for mixing 40,000 chaldron of coals with ſlates, &c.; from whence it ſeems, that the former fines and impriſonment had no effect, but that they had ſtill proceeded to cheat the metropolis and the country at large, even after thoſe ſevere meaſures of government. A. D. 1634, the king, ſolely by his own authority, impoſed a duty of four ſhillings per chaldron on all ſea-coal, ſtone-coal, or pit-coal, exported from England to foreign parts.

In 1637, one ſhilling per chaldron appears to have been paid, on the foreign vent of coals, to the mayor of Newcaſtle and corporation. Government being applied to for redreſs, letters were ſent to the biſhop of Durham, requiring him to write to the ſaid mayor, and order an immediate reſtoration of the above exaction; the biſhop's letter is dated 10th of January, 1638. In 1643, when the Scots beſieged Newcaſtle, all the coal-mines were, it is ſaid, ordered to be ſet on fire, which was prevented by general Leſlie, who took the veſſels by ſurprize. In 1648, coals were ſo exceſſively dear in London, that many of the poor are ſaid to have died for want of fuel. In November 1653, articles were again exhibited

hibited againſt the town of Newcaſtle, concerning the coal-trade; and the cauſe, as uſual, was given againſt them. About this time the port of Sunderland appears to be riſing into importance. In 1667, coals are ſaid to have been ſold in London for above 20*s.* a chaldron; about 320 keels were at that time employed upon the river Tyne, in the coal trade, each of which carried annually 800 chaldrons on board the ſhips. To adjuſt the difference of meaſures it muſt be noted, that 16 chaldrons of Newcaſtle, are equal to 31 of London pool meaſure, according to Mr. Eddington. In 1658, the cuſtoms upon all coals exported, were let to Mr. Martin Nowel at 22,000 pounds per annum, of which ſum 19,783*l.* 14*s.* 8*d.* were for the coals of England, and 2,216*l.* 5*s.* 4*d.* for thoſe of Scotland. Commiſſioners were now appointed by the lord protector, under the great ſeal of England, for the meaſuring of keels, which was performed in a new and better manner than had been before known. In December 1667, the parliament made an order, that the price of coals, till the 25th of March following, ſhould not exceed 30*s.* per chaldron; and by an act made that year, after the great fire in London, a duty of one ſhilling per chaldron was granted to the lord mayor of that city, to enable him to rebuild the churches, and other public edifices. This, however, being inſufficient, it was made three ſhillings, to continue twenty years. In 1677, Charles II. granted to the duke of Richmond one ſhilling per chaldron on coals brought to London, which was continued in the family till the year 1800, when it was purchaſed by government, for the annual ſum of 1,900*l.* payable to the duke and his ſucceſſors. This duty at preſent produces to government 2,500*l.* annually. At the end of the ſeventeenth century, 1400 ſhips are ſaid to have been employed in exporting yearly from Newcaſtle, two hundred thouſand chaldrons of coal, Newcaſtle meaſure, which was about two thirds of the whole trade. The over-ſea trade in this article, at the ſame time, employed nine hundred thouſand tons of ſhipping. In 1710, a duty was laid upon coals for building 50 churches; a curious and particular account of the monies collected by duties on coal, for the building of St. Paul's church, in London, from October 1, 1668, to May 5, 1716, is preſerved in the Antiquarian Repoſitory, vol. ii. page 40. In the year 1741, a drawback was granted on the duty on coals, uſed in fire-engines for working the tin and copper mines in Cornwall. Mention occurs in 1758, of a machine invented by Michael Meninzies, eſq. by which coals were drawn up, not by the ſtrength of horſes or of men, but by the deſcent of a bucket full of water, of a weight ſuperior to that of the coals drawn up, lifting a corve of ſix hundred pounds weight, out of a pit about fifty fathoms deep, in two minutes. A machine, nearly ſimilar, was afterwards erected at Worſley, by James Brindley, on the duke of Bridgewater's canal, and is mentioned in our article Canal. See alſo *bucket* Engine. In the year 1764, there were exported from the river Tyne, for London, and coaſtwiſe, twenty thouſand chaldrons of coals, and forty thouſand chaldrons of London meaſure for foreign parts, more than had been exported in any one year. From the years 1770 to 1776, were ſhipped to London, and other parts of Great Britain, 351,000 chaldrons of coals, of which 260,000 were ſent to London: to the Britiſh colonies and plantations, 2,000 chaldrons; and exported to foreign parts, 3,700; in all, averaging 380,000 chaldrons, Newcaſtle meaſure, per annum. The weight of theſe, at 53 cwt. per chaldron, is one million, ſeven thouſand tons; the duty paid to the crown at the ports of diſcharge, on 351,000 chaldrons, at 5*s.* per chaldron, is 167,000 pounds.

In 1776, from a note communicated by the ſurveyor of the cuſtoms of Newcaſtle, we find, that 14,000 chaldrons were exported in that year from Blyth; 18,000 chaldrons from Hartley Haven; 350,803 chaldrons from Newcaſtle, coaſtwiſe.

The trade, thus rapidly encreaſing, acquired its preſent importance. The following account of coals exported from the river Tyne, in the years 1802, 1803, 1804, and 1805, will give an idea of the amazing extent to which it is now carried.

	Coaſtwiſe.	Over-ſea.	Plantations.
In the year 1802	494,488	41,157	2844
1803	505,137	42,838	1,516
1804	579,929	48,737	3852
1805	552,827	47,213	2360

We do not here include the quantity exported from the harbours adjoining near to Newcaſtle, *viz.* Sunderland, which exports, annually, about three hundred thouſand chaldrons; and Blyth and Hartley, which alſo export conſiderable quantities; neither do we notice the proportion conſumed in the town and neighbourhood of Newcaſtle.

It is calculated, that the ſum expended in materials for boring and ſinking for coal, ſuch as wood, iron, ropes, &c. independently of the money paid for the excluſive privilege of working, amounts, in ſome collieries, to upwards of 30,000 pounds per annum. By a calculation lately made, it is ſuppoſed that 64,724 people are employed by the coal trade on the rivers Tyne and Wear. See theſe under our article Canal. The following is a calculation of the capital employed in the ſame trade.

In the collieries -	1,030,000
In ſhipping - -	1,400,000
Capital employed by the London coal-merchants -	700,000
Total	3,130,000

From this detail, the coal-trade muſt appear of the utmoſt importance, not only in a local, but in a national point of view, as a nurſery of excellent ſeamen for the Britiſh navy; and as the means of employment for many thouſands of induſtrious working people. Beſides the important advantages already enumerated, others deſerve to be noticed. Coal is in many reſpects, and in a very high degree, uſeful to the landed intereſt, not only by greatly enhancing the real value of thoſe lands in which it is found, and thoſe through which it muſt paſs, from the works to the place where it is ſhipped, but from the general improvements which it has occaſioned, in conſequence of the wealth it has brought into the country.

An act of parliament paſſed in 1803, as hereinafter mentioned, for preventing the mixing of coals of different ſorts together, by the dealers, before delivery in London and its environs; and for that purpoſe, it required the name of the coals contained in each ſhip's cargo to be certified to the buyers. It were much to be wiſhed, that ſome better criteria could have been adopted for aſcertaining the different ſorts of coals (the worſt of which often are, or rather ſhould be, ſelling in London at two thirds of the price of the beſt ſorts, or leſs,) than merely the names of the ſeveral pits' mouths out of which they were drawn; when it is well known, that all the deeper pits are ſunk through ſeveral veins of different qualities, and ſometimes have one of theſe veins in work, and ſometimes another, or perhaps ſeveral of them at the ſame time; whence the facility ariſes, of ſending better or worſe coals to market under the ſame name, according as the relative prices of good and bad coals may induce: could not the names of the different veins which have diſtinct qualities, have been certified, along with the coals dug therefrom, inſtead of the arbitrary,

trary, and perhaps worse than useless name of the pit, containing several veins exactly the same with, and actually opening into the works of the neighbouring pits? The following is an alphabetical list of the names of the different cargoes of coals published in the newspapers, as sold at the coal-exchange, London, during a considerable period, with the name of the river, canal, or port from which they were put on ship-board, after being conveyed thither by rail-ways, &c. (see our article CANAL) and a series of numbers, expressing the number of times that each name appeared among the coal-exchange sales of the day, during the period alluded to.

The number of the different sorts of coals as above, which were in one day on sale in the market, on four particular occasions, within the above period, amounted to 24; on three market days, there were 23 different sorts sold; on three days, 22 sorts; on two days, 21 sorts; on eight days, 20 sorts; on seven days, 19 sorts; on 10 days, 18 sorts; on 18 days, 17 sorts; and on 235 market days, cargoes of from 10 to 15 different sorts of coals, were reported as sold in the London market.

From the above table, the proportionate frequency of demand and facility of supply in London, for different sorts of coals, appears to have stood as follows, *viz.* Wall's end, Bigg's main, Hebburn main, Heaton main, Bourn moor main, Willington, Benton, Walker, Montague main, Hartley, Blyth, Hollywell main, Pontop (Windsor's), Tanfield moor (Pitt's), Russel's main, Wylam moor, &c. The order of the different sorts of coals, as to price per chaldron, on ship-board in the pool, have, on several occasions, stood as follows, beginning with the highest, *viz.* Wall's end, Percy main, Bigg's main, Heaton main, Hebburn main, Kenton, Walker, Willington, Benton, Montague main, Adair's main, Eighton main, Cowper main, Tanfield moor, Pontop, Brandling, Blyth, Bourn main, Team, Hartley. Newbottle, Russel's main, Bedford main, Hollywell main, Wallbottle, &c. These prices are of course subject to vary considerably, according as the vessels arrive in considerable numbers or not, with the sorts which happen to be at that time in demand. We have been at considerable pains in collecting the above particulars, in order to throw all the light in our power upon a branch of commerce, of the first importance in a national point of view, but particularly so to the metropolis, whose prosperity and comforts so much depend upon it. In Eddington's "Essay on the Coal Trade, 1803," many highly useful particulars on this subject will be found.

By 30 C. II. st. 1. c. 8. and 6 and 7. W. c. 10. and 11 G. II. c. 15. a penalty of 10*l.* is enacted, for defacing marks on keels, boats, waggons, &c. used for the carriage of coals in the ports of Newcastle, Sunderland, &c.; and by 15 G. III. c. 27. extended to the other parts of this kingdom. By 31 G. III. c. 36, regulations are enacted to the same purpose; and any person convicted of removing, defacing, or destroying such marks, is subject to the forfeiture of a sum not less than 40*s*, and not exceeding 5*l.* By 12 Ann. st. 2. c. 17. every coal-bushel shall be round, with an even bottom, be 19½ inches from outside to outside, and contain one Winchester bushel; and all sea-coal and culm, chargeable with any duties by the Winchester measure, shall be charged, sold, measured, and paid by the chaldron, containing 36 such bushels heaped up. By 17 G. II. c. 35, three justices may set the retail price of coals, after landing in any place to which the 16 and 17 G. II. respecting the price of coals brought into the river Thames, doth not extend, as they shall judge reasonable. Concerning the weights, measures, and prices of coals, especially in and about London; and also concerning the duties upon them, there are various regulations enacted by about 40 different acts of parliament, which

which we shall not recite. The stat. 43 G. III. c. 134, which is an "act for establishing a free market in the city of London, for the sale of coals, and for preventing frauds and impositions in the vent or delivery of all coals brought into the port of London, within certain places therein mentioned," situate within the distance of 25 miles from the Royal Exchange, in the city of London, empowers the corporation of London to purchase the coal-exchange in the said city, and regulates the mode of indemnity to those whose buildings may be requisite for the purposes of the said act. For preventing the sale of one sort of coals for another, the vender and dealer shall forfeit, for every such offence, 20*l.* per chaldron so sold; and such vender or dealer shall not be subject to any penalty inflicted by the 3 Geo. II. c. 26, on every person who shall knowingly sell one sort of coals for, and as a sort of coals which they really are not; provided always, that no ship-owner, master, or other person, having the care or command of any vessel within the said port of London, shall be subject to such penalty in respect of any number of chaldrons exceeding 25 chaldrons, for the same cargo of coals. This act directs, that no coal-meters or coal-heavers shall be unnecessarily detained on board a ship, and settles how the wages of coal-heavers shall be paid; it also requires, that ship-meters shall give certificates of the coals delivered in each lighter; and that no fractional part of five chaldrons shall be delivered into any room of a barge, under a penalty of forfeiture in the first case, of a sum not exceeding 10*l.*, and in the latter not exceeding 20*l.* This statute further enjoins and prescribes the mode of remeasuring coals by the vat; and also enacts, that in case the coals so remeasured shall not amount to the quantity mentioned in the certificate of such ship-meter as required by this act, the coal-meter, who measured them from the vessel into the craft, shall, for every bushel found deficient, if the deficiency be not equal to three bushels in five chaldrons, forfeit 5*s.* per bushel, and if such deficiency shall equal or exceed three bushels in five chaldrons, then such meter shall forfeit 5*l.* per bushel; and also the expences of placing the vat for the remeasurement. Carmen are required to carry a bushel measure in their carts, of the form, size, and dimensions directed by the 12 Ann. c. 17; and the carmen, not having such measure, shall, for every offence, forfeit not exceeding 10*l.* nor less than 40*s.*; and the vender or dealer in such coals, shall forfeit not exceeding 20*l.* nor less than 5*l.* Carmen are also to deliver a printed ticket in a prescribed form, previous to the delivery of any coals; and in default of such delivery, for every such offence forfeit not exceeding 10*l.* nor less than 40*s.* Meters are forbidden to give certificates without actually measuring the coals comprised in them, under forfeiture of a sum not exceeding 20*l.* if it shall appear upon the remeasurement of such coals, or any part thereof, that any sack shall not contain three bushels; then the vender of, or dealer in such coals, shall for every sack of coals deficient, on the remeasurement, forfeit not exceeding 40*s.* for every sack so found deficient. Every sack used for the delivery of coals within the limits determined by this act, shall measure in the inside, at least four feet two inches in length, by two feet one inch in breadth, under a forfeiture of a sum not exceeding 40*s.*; and no sack shall, after the passing of this act, be marked at the Guildhall of London, or at the exchequer at Westminster, that shall measure less than above. The penalty on carmen for driving away coals without measuring, when required, for every such offence, is a forfeiture of a sum not exceeding 10*l.*; and the vender or dealer shall incur the same forfeiture, and such coals shall be forfeited for the benefit of the poor.

From this account of coal, as an article of commerce, and the laws relating to it, we now proceed to its natural history. There are three genera or families of coal; *viz.* brown coal, black coal, and uninflammable coal.

I. Family.—*Brown Coal.*

Sp. 1. *Common brown Coal, Bovey Coal, Surturbrand,* or *bituminized Wood.* Its colour is light brownish black; it occurs in mass; its longitudinal fracture is fibrous lamellar, passing into slaty or woody, and is slightly glimmering; its cross fracture is more or less conchoidal, with a shining resinous lustre; it acquires a polish by friction, and is moderately hard. Sp. gr. 1.4, when pure, but when mixed with pyrites, it is often considerably heavier.

It burns with a weak flame, like half-charred wood, giving out an unpleasant bituminous odour; when ignited in an open fire, it leaves a small quantity of white ashes. According to Mr. Hatchett (Phil. Transf. for 1804), 100 parts yield by distillation

30.	Acidulous water.
10.5	Thick, brown, oily bitumen.
45.	Charcoal.
14.5	Hydrogen, carbunetted hydrogen, and carbonic acid.
100	

It is found in England at Bovey, near Exeter, and in smaller quantities in the island of Purbeck, some parts of Hampshire, Sussex, &c. lodged in pipe-clay. It is also found in the territory of Hesse and other parts of Germany, in Denmark, Iceland, Greenland, Italy, Faro islands, &c.

Sp. 2. *Moor Coal.* Its colour is dark blackish brown; it occurs in mass, forming thick beds, which are full of rifts and cracks. Internally, it exhibits a bright resinous lustre; its longitudinal fracture is imperfectly slaty, its cross fracture is even, approaching to flat conchoidal. It breaks into rhomboidal fragments. It is very tender, easily frangible, and of low specific gravity.

It is found in Bohemia, Transylvania, in Denmark, the Faro islands, &c.

II. Family.—*Black Coal.*

Sp. 1. *Slate Coal.* Its colour is pure black, or greyish-black, and is often iridescently tarnished. It occurs in mass, and commonly possesses a high resinous lustre. Its longitudinal fracture is slaty; the cross fracture is small-grained, uneven, passing into flat conchoidal. It breaks into angular fragments. It is soft and easily frangible. Sp. gr. 1.25 to 1.4. It contains from 57 to 64 per cent. of charcoal, from 33 to 43 per cent. of bitumen, and from 3 to 6 per cent. of earth and oxyd of iron. The bitumen is partly in the state of asphaltum, and partly in that of maltha; in proportion to the prevalence of the former, is the caking quality of the coal.

Almost all the common coals, as pit coal, sea-coal, caking-coal, bituminous coal, run-coal, rock coal, &c. belong to this species.

Sp. 2. *Pitch Coal,* or *Jet.* Its colour is velvet black. It occurs in mass, in plates, and sometimes in the shape of branches and trunks, with the true ligneous texture. It has a brilliant resinous lustre, and a conchoidal fracture. It is soft and brittle. Sp. gr. 1.3. It burns with a greenish flame and a strong bituminous odour. It occurs in Spain, the south of France, and in the Prussian amber mines, where it is called black-amber. In France, this substance is manufactured into buttons, beads, and other trinkets.

Sp. 3. *Cannel,* or *Candle-Coal, Splent Coal,* or *Parrot-Coal of Scotland.* Its colour is dark greyish black It occurs in mass, and has a glistening resinous lustre. Its frac-

ture

ture is conchoidal. It is much lefs frangible than common coal. Sp. gr. 1.23. It is very inflammable, and crackles and flies while burning. It flames much and burns quickly, does not cake, and leaves from 3 to 4 per cent. of afhes. The fplent-coal of Scotland is a coarfe flaty variety of the above, containing pyrites, and leaving, after combuftion, about 20 per cent of afhes.

Cannel coal occurs occafionally in the Newcaftle pits, in Ayrfhire in Scotland, and elfewhere, but the largeft beds of it, and of the pureft kind, are near Wigan in Lancafhire. It is an excellent fuel; it will take a good polifh, and may, with care, be turned in a lathe, into fnuff-boxes and other trinkets, which are often paffed off for true jet.

III. Family.—*Uninflammable Coal.*

Sp. 1. *Mineral Charcoal.* Its colour is greyifh black. It occurs in plates and irregular pieces. It has a glimmering, filky luftre, and a fibrous fracture. It foils the fingers, is foft and friable. It is fomewhat heavier than common charcoal, and burns to afhes without flaming. It generally occurs mixed with flate-coal.

Sp. 2. *Kilkenny Coal, Welfh Culm*, or *Stone-Coal.* Its colour is dark iron black, verging on fteel-grey. It occurs in mafs, has a bright metallic luftre. Its longitudinal fracture is flaty; its crofs fracture is fmall and imperfectly conchoidal. Sp. gr. 1.5. to 1.8.

When laid on burning coals, it becomes red hot, emits a very light lambent flame, like charcoal, and is at length flowly confumed without caking, leaving behind a portion of red afhes.

The true Kilkenny coal is harder than Welfh culm, and of a brighter luftre; it often contains pyrites, and therefore gives a fulphureous odour when burning. This fpecies of coal is found alfo in Hungary, Italy, and France.

Thefe are the moft confiderable varieties of coal commonly known; but we muft not imagine that each of them is to be met with in a pure ftate, in thofe places where they are found; on the contrary, the different qualities and proportions of their ingredients make a vaft number of other varieties, fit for different purpofes, according to the quality and quantity of thofe they contain. The various kinds of coals are often found mixed with each other under ground, and fome of the finer forts run, like veins, between thofe of a coarfer. Mr. Magellan obferved in the fine coals employed in a curious manufactory at Birmingham, that they produced a much clearer flame than he had ever feen produced from common coal, but, on inquiry, he found that thefe were picked out from the common coals of the country through which they ran in veins, and were eafily diftinguifhed by the manufacturers, though they did not afford fufficient indications of a fpecific difference. The purpofe to which they were applied, was the moulding of rods of tranfparent and coloured glafs, into fhapes proper for common buttons, which the workmen performed with aftonifhing expedition.

On fubjecting pit-coal of any kind to diftillation in clofe veffels, it firft yields watery liquor, then an ætherial or volatile oil, afterwards volatile alkali, and, laftly, a thick and greafy oil. But it is remarkable, that by rectifying this laft oil, a tranfparent, thin, and light oil, of a ftraw colour, is produced, which, being expofed to the air, becomes black, like animal oils. From this and other obfervations, the general opinion is, that all coals, bitumens, and other oily fubftances found in the mineral kingdom, derive their origin from vegetables buried in the earth, during the fucceffive proceffes of ftratification; fince it is well known, that only organized bodies have the power of producing oily and fat fubftances.

Before a coal-pit is funk, it is neceffary to explore the ground by boring, but if there are already pits in the neighbourhood, fections are obtained from them, which prevent the neceffity of doing fo.

Boring is accomplifhed in the following manner: The rods are made of iron, from three to four feet long, and one inch and a half fquare, with a folid or male fcrew at one end, and a hollow one at the other, by which they are faftened together, and as the hole formed by them increafes in depth, other rods are added. The chifel is about eight inches long, and two and a half broad at the extremity, which is fcrewed on to the end of the lower rod, and a lever or handle is put through an eye at the top of the upper rod.

The mode of operation is, to lift up the rods a little, and then let them fall, turning them at the fame time gently round; by a continuance of this motion, a hole is fretted, and worn by degrees through the hardeft ftrata or rocks. The borers can fix on handles for two, three, or four perfons to work as they find it neceffary. After they get down to a certain depth, the rods are wrought by a bracke; a box of wood is firft inferted into the ground, to keep the rods in a vertical or ftraight direction, and a triangle is erected over the fpot where the boring is to be made (which is about three inches in diameter), for the fake of drawing up the rods; they have one key, or temporary handle, for unfcrewing, and another for fecuring the rods from falling back again; they ufe a clofe wimble to bring up fludge and foft matter. When the chifel is blunted, or has cut down four or fix inches, the rods are lifted up, either all together, if there be convenience, or by pieces, when a key is ufed to keep the rods from dropping down the hole; the chifel is fcrewed off, and the wimple or fcoop fcrewed on. This being put down, brings up afterwards the duft or pulverized matter of the ftratum through which the chifel has cut, and fhews as well what kind of matter they are boring in, as the exact depth thereof.

A confiderable improvement in this effential operation was made a few years ago, by Mr. James Ryan, a gentleman of Ireland, for which he took out patents in 1805; a copy of that for England may be feen in the 2d feries of the "Repertory," vol. vi. p. 324; this confifts in ufing a cylindrical cutter, fomething like the furgeon's trepan-inftrument, by which a core, or folid and unbroken piece of each ftratum, is cut, and by other tools brought vertically to the furface, in the exact pofition as to the cardinal points, in which it ftood in the ftrata, and thus the quantity and direction of the dip, as well as the exact nature of the ftrata or meafures, are correctly afcertained, the former being moft effential circumftances towards determining the proper place to fink an engine-fhaft, for draining the bed of coals intended to be worked. The borers and apparatus of Mr. Ryan are calculated to form a hole of any fize, from eight inches to near as many feet in diameter; fome of two feet diameter have, we are told, been actually funk thereby, to a confiderable depth, and anfwer the purpofes of pump and air-fhafts, and that one, nearly eight feet in diameter, is now finking thereby in Ireland! In April, 1807, Mr. Ryan prefented a complete fet of his apparatus to the Board of Agriculture in London, and bored a hole of fome depth therewith near Kenfington, under the infpection of fome of its members, the cores or borings therefrom, being exhibited to the Board, and lodged with the apparatus in their repofitory, they voted a pecuniary reward to Mr. Ryan. From the apparent importance

portance of this diſcovery to mining, but to coal-finding in particular, we were induced to wiſh, to give an accurate deſcription and drawings in this place of Mr. Ryan's apparatus and proceſs, but found the time too ſhort, after the Board of Agriculture became poſſeſſed of the ſame, to do it here; under the article MINING, we ſhall endeavour to give them in the further ſtate of perfection, in which practice will doubtleſs then preſent the ſame.

Boring is of the utmoſt uſe and importance in collieries, for by boring previouſly to the ſinking of a pit, the owners procure moſt eſſential data on which to proceed, being informed before hand of the nature of the earth, minerals, and waters through which they have to paſs, and knowing, to an inch or ſo, how deep the coal lies, as well as the quality and thickneſs of the ſtratum bored. The boring notes of collieries are the grand arcana of the coal-mining trade, which the owners ſometimes diſlike to diſcover to the prying eyes of the philoſopher. They have, however, been occaſionally exhibited, which gives us an opportunity of laying before our readers an account of what relates to the boring of two of the principal collieries in the neighbourhood of Newcaſtle.

Section of the Strata South of the Main Dike in MONTAGUE MAIN Colliery, $3\frac{1}{2}$ Miles above Newcaſtle.—The Numbers in the firſt column on the left-hand form an Index, from which it will be immediately perceived, where the ſame ſtrata occur; the ſecond column contains the number of the ſtrata, the third the names of each, and the fourth, or numeral columns, expreſs the thickneſs of each ſtratum in Fathoms, Yards, Feet, and Inches.

From the foregoing ſections will be ſeen, the various ſorts of ſubſtances through which the miner, near Newcaſtle, has to paſs, before he comes to the object of his purſuit: theſe ſubſtances we may divide into ſix different claſſes, of each of which we will give an account in their order.

1ſt. Whin-ſtone; the ſtrata thus named are the hardeſt of all others, ſo that angular pieces of it will cut glaſs. It exhibits, by fracture, the appearance of large grains of ſand, half vitrified. It can ſcarcely be wrought, or broken in pieces by common tools, without the aſſiſtance of gunpowder; it decays a little by being expoſed to the atmoſphere, leaving a brown powder; in the fire it cracks, and turns reddiſh-brown. Each ſtratum is commonly homogeneous in ſubſtance and colour; the moſt common of which are black or dark blue, yet there are others of it aſh-coloured and light brown.

2d. Poſt-ſtone, is a free ſtone of the hardeſt kind, of a very fine texture, and when broken, appears compoſed of the fineſt ſand. It is commonly found in a homogeneous maſs, though variegated in colour, and is not ſubject to injury from expoſure to weather: there are four varieties of this ſtone; 1ſt. The white-poſt, which, in appearance, is like Portland-ſtone, but conſiderably harder. This is ſometimes found having brown, red, or black ſpots. 2d. Grey-poſt, which has the appearance of a mixture of fine black and white ſand; it is often variegated with brown and black ſtreaks, the laſt mentioned look like ſmall clouds compoſed of particles of coal. 3d. Brown or yellow poſt is often met with of different degrees of colour, moſt frequently that of light ochre or yellow ſand. It is as hard as the others, and ſometimes has black and white ſtreaks. 4th. Red-poſt is generally of a dull red colour. It is often ſtreaked with white or black, but is rarely met with. All theſe lie in ſtrata of different thickneſſes, but commonly thicker than any other ſtrata. They are ſeparated from each other by ſmall partings of coal, of ſand, or of ſoft matters of different colours, which are very diſtinguiſhable.

3d. Sand-ſtone; this is a free ſtone of a coarſer texture than the above; it is eaſily pervious to water, and when broken, is of a coarſe ſandy texture. It is friable, and readily moulders to ſand when expoſed to the air and rain. It has frequently white ſhining ſpangles, or plates of mica, in it, and pebbles, or other ſmall nodulous ſtones incloſed in its maſs; of this there are two kinds, diſtinguiſhed by their colours grey and

and brown. It is found in considerable thickness with but few partings, which are sandy or soft. It is sometimes in layers as thin as the common grey slate.

4th. Metal-stone; this is a tolerably hard stratum, next in point of hardness to sand-stone, solid, compact, of considerable weight, of an argillaceous substance, interspersed with nodules or balls of iron ore, and yellow or white pyrites. The surfaces of its strata are hard, polished, and smooth. When broken, it has a dull dusky appearance, is of a fine texture, like hard, dried clay mixed with particles of coal. Though hard in the mines like the sand-stone, it moulders when exposed to the action of the air. Its colour varies from black to light brown or grey; it lies in strata of various thickness.

5th. Shiver; this stratum is more frequently met with in collieries than any other; it is known to the miners under the names of black shiver, black metal, or bleas; the black is the most common, it is softer than metal stone, and, in the mine, is rather a tough than a hard substance. It is easily separable by the multitude of its partings. It breaks into long small pieces when struck with force, which, on examination, present the figures of small irregular rhomboids, each of which has a polished glassy surface; when broken across the grain, it exhibits a dry laminated texture, like exceedingly fine clay. It is very friable, feels to the touch like an unctuous substance, and dissolves in air or water to a fine black clay; and, like the last mentioned, it sometimes contains nodules of iron stone, often even beds of iron-stone are found in it. The colour of the shiver is not confined to black; it discovers brown, dun, and grey colours, and a variety of shades according to the proportions of each. Its strata are parted from each other by lamina of spar-coal, or other matter; as may be seen by the foregoing section.

Many of these strata are considerably thick, being frequently found from 100 to 200 feet in depth, or upwards, of nearly the same kind of matter throughout, whilst others again are of the least imaginable thickness. They are all divided or parted from each other, either by an even, smooth, polished surface, or with a very thin lamina of soft, dusty matter between them, called the parting, by which means they are easily separated; yet though the surfaces are sometimes so closely joined together, that it is with difficulty they can be separated, which is called a bad parting, they are never known to be in the slightest degree intermingled.

There are besides this principal division or parting, secondary ones also laterally, but these are not so strong or visible, and are only met with, where the texture is not of a uniform hardness or colour through the whole body of the strata. In almost every stratum there are other divisions called backs, which cross the former longitudinally, and cut the whole stratum through its two surfaces; these are again crossed by others, called cutters, running either in an oblique or perpendicular direction, and which cut the stratum through its two surfaces, and, together with the other partings, divide it into various figures. The softer kind of strata has in general more backs and cutters than the harder ones, which sometimes have thin partitions of dusty or soft matter, but like the partings are sometimes without any. Whenever the strata lie regularly they are thus divided, and generally extend in this manner through a large extent of country, though it is often otherwise, for that regularity is frequently interrupted, and the strata disordered by various chasms, breaks, or fissures, which are called *dikes*, *hitches*, and *troubles*, according to their dimensions, and the matters with which they are filled; first,

Dikes, or *faults*, are fissures of the largest kind, which seem to be cracks, or breaks, of the solid strata, occasioned by one part of them being broken away and fallen from the other. They generally run in a straight line for a considerable length, and penetrate from the surface to the greatest depth ever yet tried, in a direction sometimes perpendicular, and sometimes oblique, to the horizon, in which case they are said to hade or underlay. The same kind of strata are found lying upon each other in the same order, but the whole of them are sometimes greatly elevated or depressed on the one side of the dike or on the other. These fissures are frequently two or three feet wide, and at other times many fathoms. If the fissure or dike be of any considerable width, it is generally filled with heterogeneous matter, different from that of the solid strata on each side of it; sometimes with clay, gravel, or sand, sometimes with a confused mass of different kinds of stone lying edge-ways, and at others with a solid body of free-stone or even whin-stone. When the fissure is of no great width, suppose two or three feet, it is then usually filled with a confused mixture of the different matters which compose the adjoining strata, consolidated into one mass. If the dike runs or stretches north and south, and the same kind of strata are found on the east side of the dike, in a situation with respect to the horizon, 10 or 20 fathoms lower on the other side, it is then said to be a dip dike, or down-cast dike, of 10 or 20 fathoms to the eastward; or counting from the east side, it is then said to be a rise dike or upcast, of so many fathoms westward. If the strata on one side are not much higher or lower with respect to the horizontal line, than those on the other, but only broken off, or removed to a certain distance, it is then said to be a dike of so many fathoms deep, and from the matter contained between the two sides, it is denominated a clay, a stone dike, &c. There are some, though they are not often met with in the coal countries, whose cavities are filled with spar, ores of iron, lead, or other metallic or mineral matters; and it is pretty well known, that all metallic veins are nothing else than what in the coal countries are called dikes. It generally happens, that to a considerable distance on each side of the dike, all the strata are in a kind of shattered condition, very tender, easily pervious to water, and debased greatly in their quality, and in their inclination to the horizon often altered.

2dly. A *hitch* is only a dike of smaller degree, by which the strata on one side are not elevated or separated from those on the other more than a fathom. These hitches are denominated in the same manner as dikes, according to the number of feet which they elevate or depress the strata.

3dly. *Troubles* or bends may be called dikes of the smallest degree, for they are not a real breach, but only a tendency towards it. The strata are generally altered by a trouble or bend from their regular direction to a different one. When the regular course of the strata is nearly level, a trouble will cause a considerable ascent or descent; where they have, in their regular situation, a certain degree of ascent and descent, a trouble either increases or alters it to a contrary direction; and a trouble has these effects upon the adjoining strata in common with dikes, that it greatly debases them from their original qualities; the partings are separated; the backs and cutters disjoined, and their regularity disordered; the original cubic and prismatic figures, of which the strata are composed, are broken, the dislocation filled with heterogeneous matter, and the whole strata are reduced to a softer and more friable state.

Notwith-

Notwithstanding that the dikes and hitches, or faults, as they are as generally called, are filled with extraneous matters, in a considerable degree of disorder, yet there generally is a *leading*, as the miners call it, or streak of imperfect and mixed coal, which leads or directs to the vein on the other side of the fault, whether the same be higher or lower, and by which they are in a considerable degree directed, in cutting the fault to recover their vein; in very considerable faults, like that on the north of Newcastle, which drops the strata 540 feet, it is not probable that any leading can be traced. In the coal-mines near Bath, there is a fault which has altered the level of the same vein of coals, much more than in the above case.

By the sinking of the shaft, which is a narrow, perpendicular passage, a communication is opened with the various strata above-mentioned, and the different veins of coal. The strata of this fossil are seldom or never found to lie in a true horizontal situation, but generally have an inclination or descent, called, as before noticed, the *dip*, to some particular part of the horizon. If this inclination be to the east, it is called the east dip and a west rise, and according to the point of the compass, to which the dip lies, is it denominated. This inclination, or dip of the strata, is found every where; in some places it varies very little from the level, in others very considerably, even so much as to be nearly in a perpendicular direction; but whatever degree of inclination the strata have to the horizon, if not interrupted by dikes, hitches, or troubles, they are always found to lie in the regular manner first mentioned. They generally continue upon one uniform dip, until they are broken or disordered by any of the above interruptions. Wallis, in his "History of Northumberland," tells us, that the strata in that part of the island generally rise to the north-west and dip to the south-east. Dr. Stukely, in his "Itin. Curios." 1725, says, that some of the coal-works in the same country dip full east; but it is plain, he adds, that south-east is the natural dip. As those at Whitehaven, inclining south-west, receive, he supposes, a counter-bias, as being on the west side of the island; he further observes, that the principal dip is to the south-east; yet in this country dips in various directions, as the fall of valles, or beds of rivers, as well as the causes above-mentioned, occasionally influence its primary bent. See *Geology*, *Plate* I. *fig.* 1. where *aa* is intended to represent the vegetable mould or alluvial matters deposited on the surface of the regular strata, represented by *b*, *c*, *d*, *e*, &c. on the left-hand side of the figure. AA, and BB, are intended to show the dikes, by which the same are disjointed, depressed, or elevated, as before described; and where CC shows a hitch or smaller dike; DD, EE, FF, and GG, are the representations of troubles or bends of the strata.

Such are the usual dispositions of the strata; two principal difficulties are met with in the descent, the first is in keeping out quick-sands where they occur, and the second to keep the shaft so dry as to allow the men to work. A quick-sand is kept out by a process called "tubbing," that is forming a circle in the inside of the pit where the sand bed is, with staves of oak, each piece being shod with a sharp piece of iron; these are driven through the stratum of sand, so closely joined that no water can penetrate, and are kept in their situation by internal hoops or kirbs at certain distances; the water is drawn out now generally by a steam-engine and pump. See STEAM ENGINE, PUMP, *Pressure* ENGINE, *Bucket* ENGINE.

Through a large district of South Wales, their highly valuable veins of coals, of which an account was lately presented by Mr. Edward Martin to the Royal Society (and published in the Philosophical Transactions for 1806, p. 342, &c.) are gained at comparatively trifling expences, compared with most of the Newcastle pits; the depth of the vallies and heights of the hills in that part of the country, allowing several successive and thick veins of coals to be worked by tunnels into the hill above the level of the rivers, or springs of water, in the vallies; and the coals, and the valuable iron ore which also abounds, are let down into the boats on the canal tunnels, or as loading for tram-waggons in the tunnels below; through which they are conveyed to open day, and thence to the iron-works or place of shipping: of several of these curious works in South Wales we have given concise accounts, under the names of the particular canals, railways, &c. in our article CANAL; and we shall take occasion, as the names of them occur in our work, to give several material additions and corrections which have come to our knowledge, principally through the kindness of Mr. Martin above mentioned, since that article was put to press, so as to render the same, we hope, quite complete.

In the environs of Glasgow there are considerable coal-mines of excellent quality, which are also worked at an easy expence; they are found under beds of quartzose freestone, which in some mines are more than 140 feet thick; it adheres to the freestone, without any intermedium. The coal appears at the depth of 30 feet from the surface, in scattered lines running in an irregular manner through the midst of the freestone; then follow beds of the same stone without the least vestige of coal, but as the beds descend, the coal reappears in small straggling and interrupted seams from three to four inches thick; these are again succeeded by an unmixed mass of freestone, which falls through a depth of more than 40 feet, and terminates in solid and continued beds of coal. It is much to be regretted that the operation of boring is held in so little estimation in Scotland, but the reason is very obvious; in England it is made a distinct trade, and is conducted by men of information, who have been regularly brought up to the business: in Scotland it is effected by any common workmen about the pits, possessing neither information nor experience, and their accounts are consequently so confused, imperfect, and equivocal, as to merit no confidence whatever.

The great and universally felt importance of its veins of coals to this country, makes us again regret our inability, at present, to lay before our readers, any more than a few of the principles, of the modern and yet unpublished discoveries of Mr. William Smith, on this and other subjects connected with the stratification of the British islands (see our articles *Structure of the* EARTH and STRATIFICATION.) It is confessedly of the first importance, either to the inhabitants of a district in general, or to the owners of the soil in particular, to be able to detect and work such veins of coal, as may exist under their soil; and hence we find on inquiry in the neighbourhood, that almost every common, moor, heath, or piece of bad land, in parts where coals are scarce, have at one time or other been reported by ignorant coal-finders to contain coal: how many times, for instance, have our grandmothers and nurses, repeating their stories, told us, that plenty of coals might be dug at Blackheath, near Woolwich, and on other commons near London, if government had not prohibited their being dug, for encouraging the nursery of seamen, &c. Our inquiries, and those of Mr. Smith, have brought to light hundreds of instances, where borings and sinkings for coals have been undertaken in such situations, and on such advice, in the southern and eastern parts of England, attended with heavy, and sometimes almost ruinous, expences to the parties, though a source of profit to the pretended coal finders, who, or some of their never-failing race of successors, equally sapient, have in many instances been able to return to the same spot or or neighbourhood, and perfuade a new proprietor to act again the fame farce, and fquander his money on an unattainable object; for fuch, we can without hefitation pronounce, the publication of Mr. Smith's map and fections of England will prove it to be. This gentleman, more than 15 years ago afcertained, by an actual examination of the country, that the ftratum on which London ftands, is the higheft but one (the Bagfhot-Heath Sand) in the Britifh feries of ftrata, and that whether we proceed from London directly for the Newcaftle coal mines, in a direction not greatly to the weft of a north point, or to thofe in Somerfetfhire, near Bath, lying in an cafterly direction, or rather fouth of it, from the metropolis; or whether we travel thence to the neareft coal mine, lying in any intermediate direction, as in the counties of Durham, Yorkfhire, Nottinghamfhire, Leicefterfhire, Warwickfhire, Gloucefterfhire, &c.; on a careful examination we fhall find, the very fame fucceffion of ftrata occurring upon the furface, and may eafily fatisfy ourfelves, by an examination of the quarries, pits, and even of the hollow roads and ditches, which are every where to be found, of the identity in the nature of the various ftratified matters, as fand, chalk, marle, clay, limeftone, &c.; and of the exact occurrence of each in the fame order, as we proceed outwards from the metropolis. A more particular examination will next fatisfy us, that thefe appearances are occafioned by the feveral ftrata which we have mentioned, fucceffively rifing towards the north weft, (and confequently dipping in the contrary direction) generally fpeaking, and ending one after another, with very curioufly indented or fingered edges, after which the fame ftratum never occurs again: the chalk ftrata, for inftance, will be quitted near Dunftable, in the road to Warwickfhire, and never be feen afterwards on the furface, or be found funk to in any pit or excavation during all the remainder of the journey, or even in purfuing one in the fame direction, to the utmoft limits of the Britifh iflands; and, though we fhall, in fuch an examination, meet with a number of different fands, clays, and other ftrata, which may feem at firft fight to be recurrences of the fame ftratum, after it has rifen to the furface and ended; yet, on examining two of fuch more minutely, we fhall find, either the ftrata lying in undifturbed contact with them above and below, to be different in the two cafes, or their vifible or chemical qualities to differ, their thickneffes to vary, or, that the fame particular fpecies of organic remains are not found imbedded, or their impreffions left in one of the ftrata, as are obfervable in the other: wherever, on the contrary, thefe circumftances concur, they may be faid to prove the identity of any ftratum, at however diftant points it may be compared; and for fhortening our inquiries for fuch purpofe, fcience happily prefents us with the profpect of fimilar advantages, to thofe poffeffed by the botanift of the prefent day; who, inftead of examining all the parts of a plant fuppofed to belong to particular genera or fpecies, proceeds at once to examine fome one or two of them, which the writings of former botanifts have fhown to be effential characters of that particular plant; and it is no unreafonable hope now to form, that the effential characters of each of the moft remarkable and ufeful ftrata in the Britifh feries, will ere long be generally known to mineralogifts, fince they have become fo to fome particular individuals. Each particular ftratum appears to us, to have formed part of one vaft plane, with a flight inclination towards the fouth-eaft, or nearly, and with great extenfion in the directions of N.E. and S.W. in thefe latitudes; prior to the truly enormous violence with which the earth has fince been diflocated and broken, during the formation of the dikes, faults, hitches, and troubles, which we have had occafion more particularly to mention in this article, and fome greater ones, which we fhall have future opportunities of mentioning, particularly that by which the whole of the land of England, fouth of the river Thames, has been difturbed and broken from its original pofition (dipping S.E.) into one, in which all the ftrata north of a line paffing not far from Haftings, Battle, Eaft Grinftead, Guildford, &c. have now a much greater dip, nearly at right angles thereto, or N.E.; while, on the other, or fouth fide, they have juft a contrary or S.W. dip; but with as many local deviations or partial dips in each cafe, as are ufually to be found, and which fometimes vary, perhaps in feveral directions, many times in travelling a mile, and yet on the whole, the ftrata keep rifing as above, the planes being the longeft in one particular direction.

The organic remains, or exuvia of different animals, and the remains of plants, are found lodged in our ftrata in the greateft abundance, and, to fuperficial obfervers, appear to have no method or arrangement therein; but, on a clofer examination, and taking care to notice the minuter differences in thefe organized remains, it will be found, that each particular kind, either alone, or mixed with one or more diftinct kinds, occupies a certain thicknefs of ftrata, fometimes but an inch, or lefs, and fometimes many feet, but extending to the greateft diftances in the plane of that ftratum, and that either above or below thofe limits, the remains will be found to be different, or none are found; hence the layers of fhells, plants, &c. become the moft ufeful, as well as certain, criteria of the identity of ftrata; thefe often changing, where the obvious qualities of the ftrata appear unchanged, by which means they divide thick ftrata into thinner ones, and furnifh us with fo many more afcertained or known points in the progreffion of ftrata; which, in the confined operation of finking a fhaft or well, is of the greateft importance, but particularly fo in boring, for afcertaining the ftrata. See Philofophical Magazine, vol. xxv. p. 45.

We have been led to enter thus far into Mr. Smith's theory of the ftratification, in order to explain in this place fome part of that which relates more particularly to the finding of coal; and as the mention of organic remains has, and muft often again occur, we beg here to call the attention of our readers to three diftinct eras obfervable, relating to foffil organized bodies; 1ft, that period in which the animals themfelves, or their exuvia, and vegetables, were quietly depofited and buried, in and among the fucceffive depofitions of ftrata, taking effect according to laws, apparently as uniform and extenfive as thofe of cryftallization; 2d, a period wherein the ftrata were ruptured, torn, and wafhed by mighty currents of water, and during which great quantities of the organized remains from within the ftrata were detached, broken, and worn, and at length left with the gravel and alluvial matters, which now cover almoft every part of the furface, although, in many places, fuch alluvium is no thicker than what is called the vegetable mould; 3d, a period extending from the laft to the prefent time, in which the waves of the fea on its coafts, the currents of inundated rivers, and the other operations of nature, have, though in a very limited degree, been continuing the fame procefs of wafhing out, breaking, expofing, and wearing the original organized matters of the ftrata, thofe which had in the fecond period been depofited with the gravel and alluvium; and expofing alfo, in many inftances, organized remains belonging to an earlier part of the prefent or third period; which is further diftinguifhed, by the growth of immenfe beds of vegetable, or peaty matters on the furface, which have inclofed the remains of recent animals, vegetables, &c. mixed with the occafional depofitions of muddy waters, to which fuch have, in low fituations, been repeatedly fubject.

When, therefore, we fpeak of organized remains, without further

further explanation, we wiſh to be underſtood as meaning thoſe of the ſtrata, of the firſt era, no otherwiſe altered than by the gravity or chemical action of the ſurrounding matters; when we wiſh to ſpeak of the organized remains peculiar to the ſtrata, but diſturbed during the ſecond era, we ſhall, as Mr. Smith does, call them *gravel foſſils;* and this, whether they bear marks of breaking and wear, or not, if they are found depoſited with gravel, or among angular or worn fragments of matter near the ſurface, the evident effects of colliſion and attrition; when we have to mention the organized foſſil matters of the third era, if they appear ſuch as have been depoſited by water among gravel, and the depoſitions of water, as above mentioned, or have been buried by the labour and works of men or animals, and undergone a mineralization, we ſhall call ſuch *recent foſſils*, while thoſe which owe their burial, and probably their change and preſervation, to vegetation, ſhall be called *peat foſſils;* theſe terms and diſtinctions appear to us eſſentially neceſſary for avoiding, in theſe inquiries, endleſs miſtakes and abſurdities, into which former writers on this ſubject have been led, for want of ſuch diſcriminations. When organized matters of the preſent race, are found on or near the ſurface of the earth unchanged, at leaſt not mineralized, they will ſtill be denominated recent ſhells, bones, teeth, horns, plants, &c. and will be ſufficiently diſtinguiſhed from our recent foſſils above.

A careful examination of the ſeveral ſtrata which intervene and end, between London and any of the neareſt points mentioned as coal-diſtricts, will ſhow theſe ſtrata to be very various in their qualities, and in their thickneſſes (altogether amounting to ſeveral hundred fathoms), with no one circumſtance ſo obſervable among them, as the total abſence of diſtinct vegetable impreſſions or remains (among their numerous animal remains,) except of wood, and which, it is obſervable, are generally, we believe we might have ſaid always, found in theſe upper ſtrata in the ſeries, in caſual, detached, and broken pieces of the trunk, almoſt like chips and billets, and generally with the appearance upon them of previous rottenneſs and wear, from toſſing or floating in water; not unfrequently alſo, this ſuppoſition is ſtrengthened by the worm-holes with which theſe detached pieces of wood abound, particularly in the Woburn Sand ſtratum, where mineralized remains of the worms or animals which perforated the wood, found below the fuller's-earth ſtratum, are ſtill ſeen occupying the holes in the ſilicious wood, of which we have ſpecimens now before us. The pieces of wood found in the ſeries above the coal, are in ſtates as various as the matters of the ſtrata incloſing them; in many inſtances they are ſilicious, pyritic, or ochreous, leſs frequently, perhaps, they occur in a ſoft rotten ſtate, ſometimes like charcoal, and at others bituminized almoſt to the conſiſtence of pitch; and theſe laſt ſpecimens they are, which, when accidentally accumulated, as at Bovey-Tracey, and many other places, on the out-crop of the Purbeck pipe clay ſtratum, have been improperly denominated coal ſtrata; and in Suſſex, and other parts, have miſled the coal-finders, or perhaps rather their credulous employers, above alluded to.

This abſence of vegetable impreſſions will be found to continue in our journey outwards from the metropolis, until a remarkable ſtratum is paſſed, called by the miners in Somerſetſhire the "red earth," being a very red ferruginous earth, or ſtone, ſomething like that on which the city of Coventry ſtands: from hence, examining weſtward or northward, we ſhall find a material change take place, in the animal remains becoming very ſcarce, and vegetable impreſſions beginning to appear and increaſe, among a certain ſeries of ſtrata, called, by the miners of ſeveral counties, the "coal meaſures," which are often remarkable for their quick and varied alternations, as the two ſections of coal ſtrata or meaſures, which we have given in this article, will exemplify. For many fathoms together, among ſome of the coal meaſures, particularly in the argillaceous or coal-ſhales, ſcarcely a lamina of the ſtrata, as thick as paper, can be ſplit off, without expoſing the impreſſion or bituminized remains of ſome plant, as mentioned hereafter, many of them highly beautiful: as thoſe appearances increaſe, veins of coals, or uniform ſtrata of theſe bituminized vegetables, without the intervention of ſhale, or earthy matters, occur; theſe are often extremely thin, and have intervening ſtrata, or coal meaſures, ſometimes of conſiderable thickneſs between them, ſo that in ſome of our Britiſh coal-pits, 30 or more diſtinct and ſeparate veins of coal are ſunk through, before the "main," or moſt deſirable ſeam of coals is reached; from which, if the pit was to be farther ſunk, or if we travel weſtward or northward to the ending of the ſeveral meaſures ſunk through, and over thoſe below, we ſhall at length find theſe coal-meaſures end, and what the miners call "dead earth," or ſtrata, as diſſimilar to coal-meaſures as thoſe at the top of the Britiſh ſeries, already mentioned, will be found to ſucceed through a certain ſeries of ſtrata, but then other coal-meaſures will be found to occur again, &c. Theſe different ſets of coal meaſures traverſing the country, as now ſeen on Mr. Smith's map, have often been noticed by practical men, and by ſome writers, under the title of "runs of coal;" and that on which Newcaſtle is ſituated, probably from its early and great importance in ſupplying the metropolis, has been called the "great run." The firſt workings of all our coal has evidently been upon their out-crop, or breaking-to day, either at the ending of the ſtrata, or where the former and convulſive heavings of the ſtrata have left their edges bare, or nearly ſo: but experience has progreſſively proved, as the improvements of pumps, and machinery permitted, that the coals were better in quality, and leſs troubled, the farther they were purſued into the deep, or in the direction of the "ten o'clock ſun," from their out-crop, moſt generally: and thus the Newcaſtle mines have been progreſſively creeping nearer to the ſea, and now extend to, or under it, and ſtill find their coals improve; of which the Wall's End coals, brought to the London market, are an inſtance: in like manner, the mines on the oppoſite coaſt, near Whitehaven, for working ſeams, which the local dip of that part occaſions to deſcend under the ſea, have their works now extended near a mile under the ocean, at about ſix hundred feet beneath its bottom. Accordingly it has occurred, that mines have been begun higher and higher up, on the ſeries of ſtrata, called coal-meaſures, and, conſequently, had their pits of greater depths, and now the attempt is making at Bath-Eaſton, in Somerſetſhire, of ſinking in matters above the red earth, in hopes of there reaching the Somerſetſhire coal-veins, hitherto not worked ſo far eaſtward, or into the deep, by ſome miles, although ſome of their mines, owing to the rapidity of the partial dips are, we believe, working at the greateſt depths of any in the kingdom. An application of the principles above explained will enable any ingenious perſon to judge, whether his diſtrict is likely to contain coals, at practicable mining depths; for it ſeems an uſeleſs inquiry, whether they exiſt or not beyond this; for inſtance, whether the vicinity of London, and the more ſouth-eaſterly parts of our iſland have the coal-veins of the middle counties dipping under them, it can be of ſmall uſe to inquire; from the immenſe number and thickneſs of the known ſtrata which intervene, and contain no coals, or other very valuable matters. The very open and porous ſtate of ſome of theſe ſtrata, the chalks (more than 50 fathoms thick) for inſtance, occaſion them to be ſo powerfully ſupplied with

 water

water, as to render the profpect of finking even one fhaft through them at London, utterly hopelefs. Mr. Dodd, whofe fcheme for a tunnel in chalk under the Thames, at Gravefend, we have noticed in our article CANAL, has fince complained to the public, that the boring of one fmall augre hole, before his fhaft was funk, let up fo much water into it, that he was unable to penetrate more than 122 feet deep; what then was he to have expected, had he ever come to open the length of 900 yards of an 18 feet tunnel in this fame chalk? We hope to be excufed for thefe digreffions, as they tend, we think, to illuftrate the queftion, of the practicability of finding coals, through a large and important part of our ifland; and we fhall now proceed to the methods ufed in finking for coals.

The firft operation after finking the engine pit of a coal mine is the working or driving in the coal, and finking the firft coal pit; the fituation of which fhould be a little higher up the plane of the ftrata, or to the rife of the engine pit, that the water which collects may not obftruct the working of the coals when the engine ftops: yet it fhould not exceed the diftance of 30 or 40 yards, becaufe when the firft mine is to be driven a long way, it becomes both difficult and expenfive. After the pit is thus funk to the coal, the miner is to begin his work; he firft digs or undermines with his pick-axe, a light inftrument for hewing coal, (nearly in the fhape of an inftrument of the fame name ufed by paviors and gardeners) at the bottom, and on one fide, into the feam or ftratum as far as he can; he then forces down great pieces of coal by a wedge and mallet, taking care to leave, at proper intervals, pillars for fupporting the roof.

Fig. 2. in *Plate* I. reprefents the plan of the workings of a coal mine, where A A reprefents the main paffage or gangway, in the direction of the dip, and in which tram-plates or rails are now often laid, for the paffage of the trams loaded with coal to the pit or winding fhaft; B B, C C, D D, and E E, reprefent other parallel and ftraight paffages, between the pillars of coal, *a*, *b*, *c*, *d*, &c. *e*, *f*, *g*, *h*, &c. which are left for fupporting the roof and ftrata above.

The coal is often wrought in this manner to the limits of the mine; when thefe pillars, or fo many of them as can be got, are taken out by a fecond working, and the roof and other folid ftrata are permitted to fall down and fill up the excavation, often to the great and permanent injury of the furface of the land, and fometimes to canals, and other works, as particularly mentioned under our article CANAL.

If the roof and pavement are both ftrong, as well as the coal, and the pit only 30 fathoms deep, then two-thirds or three-fourths may be taken away at the firft working, and one-third or one-fourth left in pillars; if tender, it will require a larger proportion to be left, probably one-third or nearly one-half.

There is an overman, whofe office it is to go through the pit to examine the places which the men have wrought, to meafure their work, and to fee that the pit is free from inflammable vapour. There is alfo a deputy overman to fuperintend the pillars of coal that are left, and to fet up props or build walls, when the roof is loofe and threatens to fall. The bufinefs of the perfon called an "onfetter" is to hang the corves (ufually bafkets made of hazel rods) upon the rope to be drawn up the fhaft. Collieries are liable to an accident of a very dangerous nature, called a "creep" or "fit," when the pillars of coal are left fo fmall as to fail or yield under the weight of the fuperior ftrata, or when the pavement of the coal is fo foft as to permit the pillars to fink into it, which fometimes happens, by the great weight that lies upon them; in either cafe the folid ftratum above the coal falls and crufhes the pillars to pieces, and clofes up a great extent of the working, or probably the whole colliery.

Mr. Ryan, we underftand, propofes to cure the defect of a foft pavement, in the principal paffages, which are required to ftand for a long time, by forming them in the coal, of the form fhown in *fig.* 3. *Plate* I., or nearly approaching to elliptical; the tram-plates or rails *a*, *a*, in their bottoms occupying nearly the whole width in that part, with the undifturbed coal nearly or quite meeting under them: in this cafe it will be neceffary to conftruct two parallel paffages at a proper diftance, one for the going of the trains to the pit, and the other for their return. Another fatal accident to which coal-miners are fubject, in the vicinity of old workings between water-tight ftrata, arifes from the water contained in thefe artificial cavities, or fometimes in natural cavities or fiffures filled with loofe and porous matters, burfting in and fuddenly filling their works: the only fecurity againft this, is to bore an augre hole before the working as it proceeds, to prove the regular continuance of the coal. The collieries about Radftock, on the Somerfetfhire coal canal, have been fubject to this accident, on imprudently cutting through their faults, or dikes, which, as well as feveral of their intervening ftrata, are of water-tight matters.

There are two other evils to which coal mines are fubject; hydrogen gas called by the workmen, "fire-damp" by the explofion of which many lives are loft; and carbonic acid gas commonly called "choak damp," which is not fo fatal as the former. Hydrogen gas is principally generated, by the contact of pyrites with water in fome of the old workings of the collieries which have been neglected and not fufficiently ventilated: it there accumulates until difcovered by the occafional vifit of fome of the overmen, whofe office it is to examine the old workings called "waftes:" fometimes for want of due caution it caufes the death of many of the miners, being fet on fire with their lights. On thefe occafions the men throw themfelves on their faces to the ground to avoid the return of the blaft, as there is more danger to be apprehended from the vacuum formed by the total confumption of the inflammable gas, than from the effect which the fire has upon them. It rarely happens after an explofion that the men are much burnt; they fuffer more by the violent concuffion of atmofpheric air, rufhing into the workings to fill up the vacuum, than from any other caufe. After an accident of this kind, it is generally confidered dangerous to enter the pit for fome days, on which account it is to be feared many lives are loft which might have been faved by immediate affiftance. At Whitehaven and Workington, where the inflammable gas is very prevalent, the miners often work without candles, in driving their adits for ventilation, by the light of a flint mill, or of fparks produced fomewhat in the manner of a razor grinder's wheel: but the only effectual method of preventing accidents of this nature, is to pay due attention to the ftate of the old workings, and to caufe a thorough ventilation by the methods ufually adopted, which are the following: the air is put in motion by means of a large furnace placed near the edge of one of the fhafts inclofed in a covered building from which is a tube defcending into the pit. The heated air, thus afcending through the chimney, is fucceeded by cold from the fhaft, which in its turn is replaced from the loweft part of the mine. The whole is thus fucceffively removed, and its place is fupplied by air which finds its way from above, through another communicating fhaft open to the day. The certainty of this operation has evidently no dependence on the depth of the mine, its extent, or its form. The brifk current thus produced below, naturally takes the moft direct courfe betwixt the two fhafts. The ventilation on each fide is therefore accomplifhed, by means

means of a continued communication formed betwixt the two ſhafts in any required direction, by opening the proper avenues, and cloſing all others. A continued current is ſometimes made to paſs in this manner for twelve or eighteen miles, ſee *fig.* 4. *Plate* I. where S repreſents the ſhaft, and A the adit or working of a mine which is ſubject to damp or foul air; *a a a* is a cloſe pipe, leading from the part moſt affected to the ſurface of the ground, and there entering the lower part of a furnace, F, and aſcending through the fire therein, by the heat of which a current of air is conſtantly thrown out of the upper end of the pipe: this method is applicable, and very neceſſary, where particular and diſtant parts of the mine require ventilation; becauſe by this means freſh air can be made to deſcend down the ſame ſhaft, and along the adit through which the pipe and furnace cauſe the foul air to aſcend; for the more general ventilation of coal-mines, and where freſh air can be ſupplied by other ſhafts, as it generally can in mines at work, by means of the winding ſhaft, the water-ſhaft or engine pit, or both, a ſimpler mode is adopted, as at Worſley mine, on the duke of Bridgewater's canal, and other places, ſhown in *fig.* 5. where S repreſents the air or ventilation ſhaft, having a common roll and winch-handle erected over it, from which a cage or iron baſket, *c*, is ſuſpended by a chain, and in which a large fire of coals is conſtantly kept burning, ſome yards below the ſurface of the ground; the winch-handle is made uſe of for drawing the fire to the ſurface as often as the ſame wants repleniſhing.

Choak damp is rarely attended with any ill effects, and is eaſily diſcovered by its extinguiſhing a candle. The ſafeſt method of exploring collieries ſubject to this evil, is to walk as erect as the workings will allow; for choak damp being heavier than atmoſpheric air, occupies, of courſe, the lower part of the mine. It is more difficult to exhauſt this gas by ventilation than fire damp, as the latter aſcends, from its being lighter than atmoſpheric air, whilſt the other, by its gravity, is forced upwards with great difficulty.

It is not exactly determined by what means choak damp is generated in coal mines, but it is generally ſuppoſed to proceed from the putrefaction of vegetable ſubſtances.

After the operation of "hewing," or digging, is performed, the coals are brought to the bottom of the pit, in corves or baſkets, either drawn along the ground in the manner of a ſledge, or upon a ſmall rail or train road as they are called in Shropſhire, hooked on to a chain, and drawn or wound up by a rope to the ſurface. This is often effected by a machine called a gin, wrought by horſes. Of theſe winding machines there are various kinds; ſome wrought by water, others by the fire engine; either of the laſt named, are only convenient in ſome particular ſituations; that wrought by horſes is therefore in moſt general uſe. There are, beſides, a ſort of gins called "whim gins," and another known by the name of "macaroni gins." In the whim gin the ropes run upon two wheel-pullies over the ſhaft, the roller is at ſome diſtance, and the circular track of the horſes is not round the ſhaft. See our article *Mine* WINDING *Engine*, and *Apparatus*. To receive the coals, there are two "banksmen," who take off the corves at the top of the pit, and empty, or, as the workmen call it, "teem" them. The coals, by teeming, are diſcharged into waggons, by means of a grated ſpout, which allows the ſmall coals to go through it, whilſt the large paſs into the waggon. Boys or women attend to throw aſide the pyrites, or, as they are technically called, "braſſes," or in other places, "ſlates," which are ſold to the copperas manufacturers. See COPPERAS.

The coal-waggon has been already ſhortly deſcribed under our article CANAL; and for a fuller account, we refer to WAGGON. Our account of the waggon-ways, and rail-ways, alſo occurs under the article CANAL; and for other particulars relating to the conveyance of coals from the mines to the wharfs and veſſels: See WAGGON, RAIL-WAY, and STEATH.

Having thus given a deſcription of coal-mines, we ſhall give an account of a viſitation to a pit. That in which the beſt view is gained, and which can be entered with the greateſt eaſe and ſafety, is in the vicinity of Newcaſtle, *viz.* Eaſt Kenton colliery, the property of Meſſrs. Knowſley and Chapman. Having previouſly obtained permiſſion of a viewer, or ſome other perſon concerned in the colliery, a ſmall hand lanthorn muſt be provided, a light being neceſſary for each perſon. It is alſo adviſable to take a change of dreſs, at leaſt of upper cloaths; ſtrong boots to keep the feet dry, and an old hat. Being thus prepared, proceed to the ſteath, which is by the river ſide, about four miles above Newcaſtle, a pleaſant excurſion by water. When there, ſome of the men, who have been apprized of your coming, will aſſiſt in ſeating you on a ſet of ſmall empty coal waggons, capable of containing two perſons each, ſeven of which are drawn along a rail-way by one horſe. As ſoon as you are placed, with your candles lighted, you ſet off at full ſpeed, with a boy in the firſt waggon, for a charioteer, into a tunnel, or ſubterraneous paſſage ſix feet high, about the ſame breadth, and three miles in length. It is particularly neceſſary to guard againſt putting your hands ſuddenly out of the waggon, as the tunnel, in moſt places, is only wide enough to admit the waggon and horſes, and you are of courſe by doing ſo in danger of receiving an injury; but by ſitting quietly, you aſcend very ſmoothly, till you arrive at the place where the men are at work. At your firſt entrance into the tunnel you are ſtruck with the noiſe of the waggons, which, being faſtened with chains to each other, and going ſometimes at the rate of ten miles an hour, make a ſound reſembling thunder. The paſſage is in general hewn out of ſolid rock, compoſed of metal ſtone, a ſort of ſchiſtus. Where there is not rock, it is arched with brick or ſtone. The water from the pit runs down by the ſide of the rail-way to the river Tyne.

At intervals there are double rail-ways; and where you come to one of theſe your driver ſtops his horſe, and a dead ſilence enſues; he then calls aloud, and liſtens to hear if any loaded waggons are coming down, that they may there paſs each other; when he is paſt, your driver renews his ſpeed, until he reaches the next interval, when he repeats his call, and ſhould no anſwer be heard in return, he proceeds. If, by the negligence of the boys, the waggons ſhould meet where there is no double rail-way, the boy with the empty waggon unlooſes his horſe, which is taught to turn round, and force the waggons back with its breaſt, until they reach the double part, where they can paſs each other.

On the ſides of the tunnel you will obſerve ſeveral fungi of a pure white, which, by the heat of your hand, or expoſure to the open atmoſphere, diſſolve into water. The air up the tunnel is cold, but perfectly pure, but as you approach the workings a conſiderable degree of warmth is felt. You alight from your waggons in order to view the different operations to which your guide will conduct you.

In the upper ſeam or ſtratum, the coal is not much wrought on account of its inferior quality. Here you will ſee the ſtables for the horſes, the ſteam-engine for raiſing the coals from the lower ſeam, and the ventilating furnace, by which the impure vapours are drawn off. Here you will alſo be ſhown, on the roof of one of the lateral openings of this

this level, a variety of curious ſpecimens of plants, ſomewhat like graſſes, ferns, vetches, &c. impreſſed upon a ſort of blue ſlaty ſtone; the different plants are remarkably diſtinct from each other. There is alſo in one part the trunk of a tree, many blocks of which have been taken out to make ſeats in a neighbouring garden; as far as the ſtone has been cut, the tree has been traced even to its ſmalleſt branches, and the roughneſs of the bark is ſtill preſerved in the ſtone: the whole of this ſtratum is one uninterrupted continuation of theſe impreſſions of vegetables: it is nearly horizontal, and is 112 yards from the ſurface.

In Eaſt Kenton colliery, there are three ſhafts or perpendicular openings, for raiſing the coals. The firſt is the pit at the day, near the village of Kenton: it is circular, 56 fathoms deep, and at preſent only uſed for delivering coals for ſale at Newcaſtle. The coals are drawn up in baſkets. The bottom of this pit is on a line with the rail-way from the river. The ſecond ſhaft is eighteen and a half fathoms deep, and at a ſhort diſtance from the bottom of the firſt. It is ſquare, and juſt admits the waggons, which are drawn up and let down by the ſteam-engine. The third ſhaft is only 7 fathoms deep. After having examined the works, you may be drawn up to the ſurface by the firſt ſhaft in a baſket in about two minutes, in which ſpace of time you will have aſcended 56 fathoms. But ſhould this mode of conveyance not be approved of, you may return again by the tunnel. Brand's Hiſtory of Newcaſtle. Com. Magazine. Dr. Black's Lectures. Wallace's Northumberland. Pennant's Tour. St. Fond's Travels. Picture of Newcaſtle. Papers of the Literary and Philoſophical Society of Newcaſtle upon-Tyne. Philoſophical Tranſactions.

Coal-*balls*, balls made of coal and clay, or ſlack, for firing. Theſe balls are made with $\frac{1}{3}$ of clay, without ſand or gravel, and $\frac{2}{3}$ of *coal-duſt*, or *culm*, well mixed, and formed either into round balls or into bricks. This coal-duſt being the refuſe of the mine, makes this ſort of firing cheap. See Phil. Tranſ. N° 460. ſect. 3. See *Patent* Coal.

Coal *buſhel*. The meaſure directed to be uſed in London and other places for retailing coals, is different from the Wincheſter buſhel for corn, or malt buſhel, $18\frac{1}{2}$ inches wide, and 8 inches deep, containing 2150.42 cubic inches, deſcribed under our article Bushel. By the act of 12 Anne, the coal-buſhel is directed to be round, with an even bottom, and to be $19\frac{1}{2}$ inches diameter, from outſide to outſide, capable of containing one Wincheſter buſhel and one quart of water; of which a ſtandard is to be kept in the exchequer, and 36 of ſuch buſhels, heaped up, are to make one chaldron. By the act 43 Geo. III. the coal-buſhel was directed to be heaped up in the form of a cone, but the exact height, or proportion thereof, to the baſe or top of the buſhel ($19\frac{1}{2}$ inches) not being fixed in this act, the principal land coal-meters have, from careful and long continued obſervations of the cuſtom or practice of meaſuring coals, fixed the height of the cone at 7 inches above the top of the buſhel; this we learn from Mr. Robert Vazie, a gentleman who has laudably taken much pains, in endeavouring to introduce a bow-gage to coal-buſhels, nearly ſimilar to the bail or handle of a water-pail, which ſhould at all times, by being lifted up and ſwept over the buſhel, determine the proper quantity of the heaped part, which is now left to the diſcretion of the fillers, ſubject to the inattention or partiality of the meter, who is, or ought to be, ſtanding by. According to theſe data, the content of the coal-buſhel itſelf ($= 1\frac{1}{32}$ corn buſhel, as above) will be 2217.62 cubic inches, its depth inſide varying, from about 8 to 9 inches, according to the thickneſs of the wood in the ſides, it being the outſide diameter which is fixed by law, on account of the heaping up.

A cone of $19\frac{1}{2}$ inches diameter, and 7 inches high, will contain 696.8482 cubic inches, and therefore 2914.47 cubic inches, will be very nearly the cubic content of a heaped buſhel of coals, = 1.6866 cubic feet, = .062467 cubic yards, = 5.866365 cubic links, = .477126 ſteres or new wood meaſures of France, = $\frac{1}{36}$ chaldron, = 4 coal pecks, = 1.3553 malt, or Wincheſter buſhels ſtruck. From the above calculations, our readers will ſee, what relation the coal buſhel bears to other meaſures. By the late acts for regulating the delivery of coals in and near the metropolis, every waggon or cart uſed in delivering of coals, is required to have a lawful buſhel with it, edged with iron, to prevent wear, and ſealed; and uſing others or altering ſuch buſhels, incurs a forfeiture of 50*l.*

Coal, *Cannel*, or *Candle*. See Coal *Supra* and Ampelites.

Coal *Canal*, or *Somerſetſhire Coal Canal*, commences in the *Kennet* and *Avon* canal, about $3\frac{1}{2}$ miles above the city of Bath, and proceeds S.W. in two branches, with rail-way extenſions to the collieries N.E. of Mendip hills. See Canal.

Coal-*fiſh*, in *Ichthyology*. See Gadus *Carbonarius*.

Coal-*iſland*, in *Geography*, a village in the county of Tyrone, Ireland, where the coal works are carried on with tolerable ſucceſs. In 1800, there were five pits working induſtriouſly, and the works were not much impeded by water. There is, however, great want of encouragement; and the canal, which was made at the public expence, to the Tyrone collieries called Blackwater, has been ſo much neglected, that it is choaked up with mud and weeds. Coal-iſland is about 3 miles W. from Lough-Neagh, and 4 N. from Dungannon. M'Evoy's Account of Tyrone. See Canal.

Coal *Meaſures*, a term among miners, for the ſtrata moſt frequently alternating with beds of coal; theſe often conſiſt of argillaceous ſhale, and contain numerous impreſſions of vegetables upon them, of which there was a very curious collection in the late ſir Aſhton Lever's muſeum. See our article Coal *Supra*.

Coal *Meaſuring*. In the pool or port of London, coals are meaſured out of the ſhip into the barges, or lighters, in a veſſel or low tub, called a vat, holding nine buſhels (ſee Vat), which is heaped up by the porters who fill, until the ſworn meter, who is always in attendance, is ſatisfied with the juſtice of the meaſure, and directs the vat to be emptied over the ſhip's ſide into the room of the barge, &c. below. Out of theſe barges, &c. the coals are again meaſured by a ſtandard coal buſhel (ſee Coal-*buſhel*), in the preſence of another ſworn meter, called a land meter, and are emptied out of the buſhel into ſacks, for delivery to the buyers; a few years ago, this laſt proceſs was improved as follows:

Plate XIV. of *Mechanics*, repreſents a machine for meaſuring coals, for which Meſſrs. Simeon and Thompſon took out a patent in the year 1803. The machine, from which the drawing is taken, was erected in 1803 at the Red-croſs coal wharf, near London bridge, and has been at work ever ſince with great ſucceſs near the water-works. It is erected before the wall of the coal warehouſe, and communicates with the ſecond floor, by a large opening in the wall. The barges, containing the coals, are brought under the wall of the warehouſe, which is by the water-ſide; they are filled into buckets, and then drawn up by a machine into the houſe, where they are emptied into a wheel-barrow, and thus conveyed to the ſtage, A, *fig.* 1, in the floor of which the

the bushels, B, B, B, are placed; these bushels are of cast-iron, of the dimension directed by act of parliament; they have moveable bottoms, opening downwards on hinges toward the wall of the house, and are shut by a chain, which is fastened to the bottom, opposite the hinges, and comes up through a tube, *a*; the other end of the chain goes over, and is fastened to a wheel of cast-iron, E, mounted on a shaft, which carries similar wheels for the other two bushels; it turns on a pivot in the wall, F, at one end, and on another, working in a collar, supported in the wainscoting, G, which forms the other end of the room; the shaft projects some distance through this partition, and has a wheel, H, fixed on it, round which a rope, I K, passes; the end, K, of this rope has a ring tied to it, which is hooked on a pin in the wall, which pin is adjustable by a screw, as shown in *fig.* 2, so that when the ring is hooked on it, the bottoms of the bushels shall be close shut; *b d*, *fig.* 2, is an iron frame screwed to the wall, in which a square piece of iron, *e*, carrying the pin (on which the ring is hooked) slides; *f* is a screw turning in the frame, and passing through the piece *e*, which is tapped, so that by turning the screw by a winch, put on the square at its upper end, the pin can be raised or lowered.

The chains, D, *fig.* 1, have each a screw-link in them, by which the bushels can be all made to shut close at the same time. Beneath each bushel is a wooden hopper, L, into which the coals are emptied when the bottom of the bushel is opened, and the sacks are hung to this hopper to receive the coals; there are two small hooks at the back of the hopper, to which the mouth of the sack, M, is hooked; *h* is an iron bar, with a hook at each end, to fasten to the sack; two small cords are tied to this bar, which pass over two pulleys, and are both fastened to a ring that is hooked on a pin, driven into the hopper, in order to keep the sack's mouth close up to the hopper.

The operation of the machine is as follows: the coals are filled into the bushels by three men, and are heaped up until they touch the plummet, *d*, suspended by a chain from the ceiling; when the coal-meter, who sits before the desk, N, sees, through the window, that they are properly filled, he takes the rope, I, with one hand, and with the other slips the ring, at the end of K, off the pin, as before described; the weight of the coals, resting on the bottoms of the bushels, then causes them to open, and the coals fall into the sacks beneath; he holds down the rope, I, until the bushels are all emptied, then lets it return, and hooks the ring on the pin. The bottoms of the bushels are made to shut, by one of the spaces between the arms of each wheel, E, being filled with lead, which is equal to about half the weight of the coals; when the sacks are filled, they are placed in a hand-barrow, and are wheeled into the waggon, the stage, R, being just the same height from the ground, as the floor of the waggon, which is backed up against it.

COAL-*Mines.* See COAL. By 10 G. II. c. 32, if any person shall wilfully and maliciously set on fire any mine, pit, or delph of coal, or cannel-coal, he shall be guilty of felony, without benefit of clergy. By 13 G. II. c. 21, if any person shall convey water to any coal-work, with design to destroy or damage the same, he shall pay to the party aggrieved treble damages with costs, recoverable in any court of record at Westminster. By 9 G. III. c. 29, any person demolishing engines, waggon-ways, bridges, &c. belonging to coal-mines, or causing the same to be done, shall be guilty of felony, and be transported for seven years: the prosecution on this act being within 18 months. By 39 and 40 G. III. c. 77, any person, destroying or damaging mines or roads leading to or from the same, shall be deemed guilty of a misdemeanor, and may be imprisoned, on conviction, for any time not exceeding six months. Colliers and others, who wilfully and obstinately work in a manner contrary to their agreements, or who do not fulfil their contracts, shall, on conviction, upon the oath of one witness, before one justice, forfeit not exceeding 40*s.*, and upon non-payment, be committed to the common gaol without bail, for a time not exceeding six months, or till such penalty and costs shall be paid; and the contract shall become void. Persons convicted of fraudently walling or stacking coal, &c. shall, on conviction, by confession or oath of one witness, before one justice, be committed to the common gaol or house of correction, for any time not exceeding three months. If any person shall steal coals or implements, not exceeding the value of 5*s.*, he shall, for the first offence, forfeit not exceeding 10*s.* over and above the costs, or be committed to hard labour for one month; for the second offence, not exceeding 20*s.*, or be committed to the house of correction for three months; and for the third, or any future offence, not exceeding 40*s.*, or be committed to hard labour for 6 months. All prosecutions under this act shall commence within nine months after the offence is committed.

COAL, *Old,* an inferior sort of charcoal, made in Kent, and other places, from the roots of trees and underwood, for sale to the founders, and others, in London, who use it for some common purposes, as a substitute for charcoal.

COAL-*Orton,* or *Cole-Orton,* a rectory in the hundred of East-Goscote, in Leicestershire; it is situate very high, yet its coal-mines have attracted the rail-way extensions of canals, in two different directions, *viz.* the *Leicester* and the *Ashby-de-la-Zouch.* See CANAL.

COAL, *Patent,* is applied to a substance manufactured in Millbank Street, Westminster, under a patent, granted to Mr. Chabannes, (see *Repertory of Arts,* XV. 367.); it consists of the smaller parts, sifted out of the sea-coals, used for culinary purposes, before they are sold, mixed up with a certain proportion of dirt and sweepings of the streets, which mixture is watered and tempered together, until fit for making into small bricks, of which great numbers are set to dry in a large open-boarded shed. One or two of these coal-bricks, put into a coal-fire, are said to continue the intensity of its heat for a long time. See COAL-*balls.*

COAL-*Port,* the name given by the late Mr. William Reynolds, to a new town which he founded on the banks of the Severn river, at the entrance of the Shropshire canal. See CANAL.

COAL, *Small,* is a sort of charcoal, prepared from the spray and brush-wood, stripped off from the branches of coppice-wood, sometimes bound in bavins for that purpose, and sometimes prepared without binding.

The wood they dispose on a level floor, and, setting a portion of it on fire, they throw on more and more, as fast as it kindles; whence arises a sudden blaze, till all be burnt that was near the place. As soon as all the wood is thrown on, they cast water on the heap from a large dish or scoop; and thus keep plying the heap of glowing coals, which stops the fury of the fire, while, with a rake, they spread it open, and turn it with shovels till no more fire appears. When cold, the coals are put up into sacks for use. Small coal was formerly much more in use in London than it is at present. The siftings of charcoal are called *charm* by the London dealers.

COAL-*foot.* See SOOT.

COAL-*spirits.* Coals distilled in a retort not only afford a phlegm and black oil, but a spirit, or gaseous matter, which is

apt

apt to force the lute and break the glaffes, now known to be hydrogen gas: bladders may be filled with this inflammable air, which may be kept a confiderable time. If the bladder be pierced with a pin, and fqueezed near the flame of a candle, the gas will take fire, and afford an amufing fpectacle. See Phil. Tranf. N. 452. fect. 5. See DAMPS and GAS-*Lights*.

COAL-*tar*. See TAR.

COALBROOK DALE, in *Geography*, a village of Shropfhire, about 13 miles from Shrewfbury, which exhibits to the traveller the beneficial effects of manufacture and commerce, in its celebrated iron-works, as well as a variety of romantic fcenes. The river Severn winding between high wooded hills, oppofite to the forge of Brofeley, is croffed by a bridge of one arch, 100 feet in length, and formed entirely of caft-iron, with ftrong ftone abutments, which prefents at once a ftriking effect in landfcape, and a ftupendous fpecimen of the powers of mechanifm. This was the firft iron bridge erected in England, and was caft in 1779, under the direction of Mr. Abraham Darby. Befides the communication of thefe works with the Severn river, they have a branch of the Shropfhire canal extended to connect with their rail-ways. See CANAL.

COALESCENCE, the union or growing together of two bodies before feparate. It is principally applied to fome bones in the body, which are feparate during infancy, but afterwards grow together; or to fome morbid union of parts which fhould naturally be diftinct from each other. Thus there is a coalefcence of the fides of the vulva, anus, and nares; of the eye-lids, fingers, toes, and many other parts.

COALITION, the re-union, or growing together of parts before feparated. See CONGLUTINATION, &c.

COAMANI, in *Ancient Geography*, a people of Afia, in the vicinity of the Paropanifiani, according to Mela; the fame with the Comani of Pliny, who probably inhabited the country called by Xenophon *Comania*.

COAMINGS, in *Ship Building*, are thofe planks, or that frame, forming a border round the hatches, which raife them up higher than the reft of the deck. Loop holes for mufkets to fhoot out at, are often made in the coamings, in order to clear the deck of the enemy when the fhip is boarded.

COANCA, in *Ancient Geography*, a town of India, placed by Ptolemy on this fide of the Ganges.

COANE, among the Greeks, a name given to a peculiar fpecies of tutia or tutty, which was always found in a tubular form. It has its name from κωνη, a word ufed to exprefs a fort of cylindric tube, into which the melted brafs was received from the furnace, and in which it was fuffered to cool. In cooling, it always depofited a fort of recrement on the fides of the veffel or tube; and this was the tutty called *coane*.

COANEPILLI, in *Botany*, Hernand. See PASSIFLORA *n. n.*

COANGO, in *Geography*, a river of Africa, in the kingdom of Congo, called *Zaire*, which fee.

COANZA, a large, deep, and rapid river of Africa, which rifes in the unknown interior parts towards the eaft; and, after receiving many rivers in its courfe, and bounding the kingdom of Angola on the fouth, empties itfelf into the Atlantic, about 9° 20′ S. lat. and about 12 leagues S. of St. Paulo Loando, the capital of Angola. It is navigable about 150 miles upwards, quite to *Cambamba* (which fee); and abounds with variety of fifh, forms feveral iflands, and has fome cataracts, one of which, in particular, bears its name. Its mouth, between the capes Palmerino and Lego, is above a league wide; and its fall into the ocean is fo rapid, that the fea is rendered muddy 2 or 3 leagues below it. Its mouth is not eafily perceived from the open fea, on account of an ifland quite covered with high trees, which lies juft before it. About 15 or 16 leagues above, it divides its waters into two ftreams, of which the fouthern is the deepeft, and moft frequented. The two chief iflands formed by this river, are *Maffander* and *Motchiama*, which fee.

COAPAIBA, in *Botany*, Marcgr. Pif. Rai. See COPAIFERA.

COARA, in *Ancient Geography*, a town of Syria, in the province called *Chalcidene*, which fee.

COARI, in *Geography*, a river of South America, which runs into the river of the Amazons, in Terra Firma.

COAS, in *Ancient Geography*, a river of India, fo called by Ptolemy, but by others called *Choes*. See COPHENES, and COW-*river*.

COASINA, a town of the French department of Liamone, on the ifland of Corfica, and chief place of a canton in the diftrict of Sartene; 5 miles N. of Cervione. The canton contains 2631 inhabitants.

COASSE, in *Zoology*. See VIVERRA *Vulpecula*.

COAST, in *Geography*, a fea-fhore, or the country, adjoining to the edge of the fea. Buffon diftributes the coafts of the fea into three kinds; *viz.* 1. High coafts, compofed of hard rocks, commonly perpendicular, and of a confiderable elevation, rifing fometimes to the height of 700 or 800 feet. 2. Low coafts, of which fome are almoft level with the furface of the water, and others have a fmall elevation and are often bordered with rocks nearly on a level with the water, which give rife to breakers, and render the approach of fhips very dangerous. 3. Downs, or coafts formed by fand, either accumulated by the fea, or brought down and depofited by rivers; thefe downs form hills of greater or lefs elevation, according to circumftances. The depth of the water along the coaft is generally proportional to their elevation; fo that a high coaft indicates a deep water, and, on low coafts, the water is commonly fhallow. See SEA.

COAST, *Gold*, fometimes called *Guinea Proper*, a province of Guinea on the coaft of Africa, fo called from the abundance of gold which it produces, is bounded by Nigritia or Negroland on the north; by the Slave coaft on the eaft; by the Ocean on the fouth; and by the Tooth or Ivory coaft on the weft. It commences at the river Ankobar, or Cape Apollonia, and extends to the Rio Volta, comprehending from 100 to 120 leagues from weft to eaft. The Gold coaft, ftretching along the fea, contains a variety of different kingdoms and ftates, *viz.* Adomir, called likewife Saku and Avira; Axim, Ankobar, Adom, likewife called Little Inkaffan, or Warthes; Jabi or Jabs; Commendo or Guaffo; Fetu; Sabu; Fantin; Acron, or Akron; Agonna, or Anguirra; Amra, or Aquamboe; Labbade; and Ningo, or Lambi. Each of thefe kingdoms or provinces has one, two, or more towns or villages on the fea coaft, between, or under the European forts and fettlements. Some of them are monarchies, having their own proper kings, and others are republics, governed by magiftrates, who are fubject to the laws and periodical changes. The gold of this country is generally found in three different kinds of places; the firft and beft in vallies, fituated between mountains; the fecond at and about rivers and falls of water; and the third at the mouth of rivers and rivulets on the fea coaft, which laft the negro women, after a fall of rain, collect, by wafhing the earth that contains it, in bowls, and thus feparating the one from the other. The negroes practife various methods for fophifticating the gold, which they obtain. One is the cafting of it into fetiches, mixed with half or a third part of filver and copper. (See FETICHE.) Another method of adulteration is that of cafting pieces

pieces of gold ſo artfully, that the external cruſt, about the twelfth of an inch thick, ſhall be pure, while the inſide conſiſts wholly of copper, or of iron. The third method by which they attempt to deceive the Europeans, is by means of a powder of coral or of copper filings, tinged ſo exactly like gold, that only ſcales can detect the counterfeit.

The natives of the Gold coaſt are in general tall, ſtraight, and well-proportioned, with oval faces, ſparkling eyes, regular and white teeth, thick eye-brows, and ſmall ears; mouths moderately large, and lips tinged with a better colour, and thinner than thoſe of the negroes of Angola. With regard to their mental faculties they have a quick apprehenſion and retentive memory, and a ſurprizing degree of ſelf poſſeſſion upon the moſt ſudden and alarming occaſions. As to their diſpoſition and character, they are, in general, extremely indolent in the exerciſe of the talents with which nature has endowed them; they are crafty, fraudulent, and diſſembling; covetous and intemperate. When they obtain a victory over their enemies, they return home dancing and ſinging; and, if they are defeated, they do the ſame round the graves of their friends and fellow-ſoldiers; ſo that a ſtranger cannot diſtinguiſh a victory from a defeat, except that after the latter they ſhave their heads. The women are handſomer than the men, ſtraight, ſlender, and well-limbed; with high cheſts, ſmall mouths, and eyes ſpirited and lively. They are cheerful and loquacious; gay in their diſpoſition, and looſe in their principles as to gallantry, but temperate in their diet. Both the men and women, when neceſſity ſurmounts their natural indolence, are ingenious, diligent, and laborious; and when they are excited by avarice or indigence, they apply themſelves with great aſſiduity to agriculture and fiſhing. Upon the whole, their natural talents are good, but their paſſions are ſtrong, their ignorance great, and they abandon themſelves to the calls of nature without dread of ſhame, that ſhield of decorum, decency, and virtue. Their dreſs is various, depending upon fancy and circumſtances; ſome wear long hair, curled, plaited, or tied upon the crown of the head in the form of a roſe, which they moiſten with oil, and tinge with different colours, and others wear it ſhort, for conveniency; or looſe, either for ornament or from negligence. Their hair, however, is generally adorned with gold fetiches; a ſort of collar, called "conte de terra," four times the value of gold; or with a blue coral, which they call "accori," eſteemed of equal value with the precious metal. Their arms, legs, and likewiſe waiſts, are ſet off with gold, conte de terra, and accori. Their uſual dreſs is a petticoat of velvet, ſilk, cloth, or ſome ſtuff; and thoſe who pretend to a taſte ſuperior to the vulgar, make their "paans" of a mixture of 50 different kinds of cloth. This paan they plait ſo artfully that it fits neat round the middle, hanging half way down the legs; round their necks they wear ſtrings of gold and coral, amounting ſometimes to 100*l.* in value; and by theſe worth among them is eſtimated, ſo that thoſe who want them are excluded the company of thoſe who poſſeſs them. The common people, as fiſhermen, &c. are very poorly attired, with a yard or two of mean ſtuff formed into a kind of petticoat, or with a girdle drawn between their legs; to which they frequently add a cap made of ruſhes, or when they can obtain it by ſtealth or intereſt, a ſailor's old hat, which they wear in hot as well as cold weather. The rage of dreſs is chiefly prevalent among the women, ſo that the ladies are loaded with gold, coral, and ivory trinkets. In the manners of all the negroes, both male and female, there is a neatneſs peculiar to warm climates, and indeed neceſſary in ſuch climates, which is a practice of waſhing their bodies twice every day, either in ſalt or freſh water. With this view they fix their habitations either on the ſea-coaſt or on the banks of rivers; and in defect of theſe, they make tanks or baths; habit rendering cleanlineſs no leſs eſſential to them than food. They teach their children to ſwim when very young: and thus they become expert divers, and are able to continue for a long time under water. So fond are they of this element, that half their time is ſpent in it, and they may not improperly be denominated amphibious.

Beſides the natural inhabitants of the Gold coaſt, there is a great number of Mulattoes, a mixed progeny, ariſing from the commerce of Europeans with the black women. This ſpurious race, it is ſaid, form gangs of thieves and robbers, void of decency, honour, honeſty, or principle, in their dealings with each other, with the negroes or Europeans. They call themſelves Chriſtians, but in reality are the groſſeſt idolaters; and their women very generally proſtitute themſelves, publicly to Europeans, and privately to the negroes.

The towns and villages of the Gold coaſt conſiſt of a multitude of little huts or cabins, diſperſed in groups, without order or deſign, and communicating with each other by narrow crooked roads, which terminate in the centre of the town or market-place. The farther you remove from the ſea-coaſt the more civilized do the natives appear, at leaſt, as to their building and mode of living. On the coaſt the towns and villages are ſituated in dry, barren, ſandy lands, or upon rocks and precipices; but, in the interior parts, they occupy the moſt delicious ſpots that can be choſen; they are better built, kept in a neater and cleaner ſtate, generally paved and better peopled.

The diet of the negroes on the Gold coaſt is neither delicate nor expenſive; conſiſting commonly of a pot of millet boiled to the conſiſtence of bread, yams, and potatoes, over which they pour palm-oil; and the diſh is garniſhed with herbs and putrid fiſh. On holidays they feaſt upon beef, mutton, and fowls. The diſh called "malaguet," which is uſed by people of a ſuperior rank, conſiſts of fiſh, corn, dough, palm-oil, and herbs, boiled in water and ſeaſoned with ſalt and pepper. The negroes, though ſomewhat temperate in eating, indulge to a great degree in drinking. The morning is uſhered in with brandy, and the evening concludes with palm-wine, mirth, riot, and tobacco, of which they are extravagantly fond.

In their marriages they have no ceremonies, nor have they any previous courtſhip, or any diſputes about marriage-ſettlements. Polygamy is allowed among them without any reſtriction beſides what reſults from humane or worldly circumſtances; however, the uſual number of wives is from two to ten, and ſeldom exceeds twenty. The women conſtitute the labouring part of the people, and are employed in cultivating the ground, and providing ſubſiſtence for the huſband, who ſpends his time idly in goſſipping, drinking, and ſmoaking. On the coaſt, however, the caſe is different; for in many towns and villages the men toil and labour for the females. The rich have two wives, exempt from ſervile employment, to whom the management of the houſe is entruſted, and who exerciſe a delegated authority over all the other women. Of the honour of theſe the huſband is particularly jealous; but as to the reſt he is unconcerned, provided that he can profit by their incontinence; for among the negroes it is not uncommon for the huſbands to derive ſupport from the voluntary proſtitution of their wives; and as the wealth of the negroes conſiſts chiefly in the number of their family, they direct their chief attention to the increaſe of their children; accordingly great reſpect is paid to a woman with child; and ſhe is delivered without much pain or or anxiety. Besides their lawful wives, the negroes often keep concubines, who are frequently preferred, and more tenderly treated than those to whom they are actually married; but their children are illegitimate, and, if begotten upon a slave, are retained as such by the heir of the father's fortune, unless he previously manumits them with the usual ceremonies; in which case they are free after his death, and enjoy every right of free-born persons. Legitimate children never inherit the fortune of parents in any kingdom on the Gold coast, except at Acra. The eldest son of a king or chieftain succeeds his father in his employment; but, besides his shield and sabre, he has no claim on any other part of his fortune. Among the negroes, masters are accountable for their slaves, and are obliged to repair the injury they commit by theft, robbery, adultery, or murder. They are likewise responsible for their sons, nephews, and other relations; and unless the imposed fine be paid, the delinquent must suffer corporal punishment, and even death, if the crime be of a heinous nature. He who debauches the wife of another man in the interior countries, is not only ruined himself, but entails destruction on all those who are connected with him by blood. If the delinquent be a slave, the punishment is a cruel death, besides a fine imposed upon the master. If a woman be caught in adultery, her life is forfeited, unless it be redeemed, at a great expence, by her relations; and the woman who indulges her passion for a slave dies, without possibility of redemption. The slave also perishes with her, and her relations are obliged to pay a considerable sum of money to the injured husband. In this case every considerable negro is his own judge. The woman, on the other hand, has no redress, if the husband should prove unfaithful. On the sea-coast all the women marry young; and many families ally themselves by marriage as soon as the children are born. Chastity, however, is held in no high estimation; for those who violate it before marriage forfeit no respect either from their husbands or the world; nay, they are esteemed the better qualified to enter into matrimony, and are consequently preferred to absolute vestals. In the countries of Eguira, Axim, Ancobar, Anta, and Adom, there are certain females who never marry, but are dedicated by profession to the public use, and formally initiated in their vocation. The negroes, though in various respects unpolished, are by no means deficient in a certain exterior politeness in all their mutual intercourse. When they first meet in the morning, they clasp each other in their arms, and pray that the day may be prosperous. Upon an accidental meeting, after they had before seen each other, and the usual compliments had passed, the negroes on the coast pull off the hat or cap; but the interior negroes do not esteem uncovering the head as any token of respect. At Elmina, when a stranger from another country is introduced, after the first compliments, the wife, or female slaves, bring water, grease, or ointment, to wash and anoint him; which office they perform with their own hands. The visits of kings and persons of superior rank, are attended with several peculiar and extraordinary ceremonies, which it is needless to recite.

Few families on the coast keep any considerable number of domestic slaves; nor do they make any great parade of them at their festivals or visits. The exclusive right of selling slaves is vested in the rich, not so much by law as from the necessities of the meaner rank, which render them unequal to the purchase and maintenance. Those who are employed in this capacity in almost all the maritime parts, consist of such as have bartered their freedom to the rich for sustenance, and are marked by them with certain signs, that attest them to be their property. If after this any attempt should be made to run away, they lose the left ear for the first trespass, the right ear for the next, and the third fault is punished either by death, or selling them as slaves to Europeans. Those who are born slaves are treated with a degree of tenderness on the coast which is uncommon in the inland countries. They are chiefly employed in fishing, agriculture, and those arts that are necessary for the support of their masters and themselves.

Among the negroes, there is a variety of mechanical arts, in which they are considerable proficients; such as making wooden and earthen vessels and plates, chair-matting, copper ointment-boxes, bracelets, necklaces, rings, and ear-rings of gold, silver, or ivory. Their chief excellence consists in the manufacture of all sorts of weapons and instruments of war, and all kinds of smith's work; their tools, however, are very rude and simple. They also manufacture gold and silver hat-bands of a very fine thread and exquisite workmanship. In building canoes of various sizes, and used for trading from one port to another, loading and unloading ships, and fishing on the coast, they are very ingenious; as well as in the use of them. Their agriculture is chiefly performed in the rainy season; the ground being at other times too hard for tillage. At seed-time they choose a convenient spot of ground, which is easily obtained with the consent of the king, who claims a nominal jurisdiction; and in three days after it is sown the whole field is covered with a beautiful verdure, and the crop is ready for reaping in less than three months. For maize they select an elevated ground; and for rice and millet, low marshy lands. The natives of the coast find it so easy a matter to dispose of all their grain, that they have established corn-markets in every village, where the current money is gold dust, cowries, and bujis. The price of grain is rated by police officers of the king's appointment; and to these markets the men and women resort early in the morning to buy or sell, or to exchange one sort of grain or fruits for another. Such are the industry and strength of the negro women that they frequently travel from the interior country six miles to market, under heavy loads, and sell their fruits or grain at the sea-port markets for European commodities, looking-glasses, bracelets, ear-rings, glass-beads, and other female trinkets, so passionately fond are they of dress and finery. The markets are exempted from all sorts of duties and imposts. At mid-day, the wine merchants bring their pots of palm-wine to market; and when the business of the day is finished, multitudes of men and women are to be met on all the roads, singing and dancing with an enviable cheerfulness, and without the smallest remaining vestige of the care and fatigue of the day. Besides these markets, they have also fairs, which regularly occur twice a-year, whither the natives resort to purchase European wares, which they transmit to the inland countries. On these occasions the women assemble in the evening to dance, sing, and make merry for an hour before they go to bed. They appear in their best habits, and the women in particular rival each other with all the emulation and jealousy of dress conspicuous among European females. Their dance is a kind of regular confusion, which, with the appearance of disorder, preserves a certain method adjusted to the music, which is composed of horns, trumpets, flutes, and other instruments. The women wear on their legs a number of small bells, which jingle as they move in their dance; and the men hold in their hands a kind of fan, made of horse-tail, or the extremity of an elephant's rump, with which they strike each other's shoulders as they pass. The dances performed in honour of the fetiche are more grave and solemn, bearing about them an air of religious devotion. At Abramboe, they have dances for eight succeeding days, in honour of the king, which they call the dancing season: to these

these there is a resort of a large concourse of negroes of both sexes; and the whole is conducted with extraordinary pomp. All the diversions among the negroes consist of these dances, music, and mock-combats, which latter often terminate tragically. Among other customs and manners that distinguish the negroes, we cannot forbear mentioning one excellent institution, in consequence of which a common beggar is not to be seen on the coast. When a negro is unable to subsist by labour, he binds himself to a master, who is obliged to supply him with all necessaries. In return he engages to defend his master with all his power, to watch his affairs, and, in seed and harvest time, to labour as a husbandman. Thus every man becomes usefully employed, and the infirm and aged are taken care of by their friends.

Among the negroes, the fear of death is a very general and distressing passion; and, accordingly, for prolonging life, they recur first to medicines and natural remedies; and when their case is deemed peculiarly dangerous, they have recourse to their superstitious religious worship, as the most effectual antidote. The priest of course diverts the patient by liberal offerings to appease the fetiche; nor does he on this occasion neglect his own interest. If the diseased person recover, the priest is sure of ample recompence. The chief medicines used by the negroes are lime-juice, malaguet, or cardamoms, the roots, branches, leaves, bark, and gums of trees, and about 30 different kinds of green herbs.

When all the arts of the priest and doctor have proved ineffectual, diligent inquiries are instituted concerning the death of the patient. Having ascertained that it has not been owing to poison or incantation, his relations are examined, whether he has been attended with due care, and the necessary offerings have been made to the fetiche and priest. Should no defect in these particulars appear, they satisfy themselves with attributing his death to his neglect of religious duties, and the performance of those rites which can alone prolong life. The priest proceeds to interrogate the deceased, and then returns to the assembly of his friends and kindred with such an answer as best suits his interest; and they are then satisfied. As soon as the patient has breathed his last, his relations unite in dreadful howlings and lamentations; and then preparations are made, by a variety of ceremonies, in which the fetiche and priest have an interest, for his funeral. Presents are made in order to obtain repose for his soul, and to secure his safe passage into the other world. In his coffin several articles of value are deposited, costly in proportion to his wealth; and when his assembled relations or friends have continued for two or three days to drink brandy and palm wine, and other ceremonies are finished, the corpse is carried to the grave, preceded by a number of young men, who continually discharge vollies of arms, till the deceased is laid in the ground. Men and women, in great crowds, follow, some dancing, some singing, and others crying or laughing. When the corpse is covered, and the grave filled, every one departs where he pleases. But the greater number usually adjourn to the house of the deceased, there to prolong their mirth and feasting. When a king, or any eminently distinguished person dies, his body is generally kept a year above ground; and, in order to preserve it from putrefaction, it is laid over a gentle fire, upon a wooden utensil, resembling a gridiron, to dry by slow degrees. Others inter their dead privately in their own houses. At the funeral of a king, several of his slaves are sacrificed in order to attend him to the other world; and especially his favourite wife. But the most abominable rite is the practice of selling those who, through age and infirmity, have been rendered incapable of labour, to become victims in these horrible solemnities. The negroes usually build a little hut, or plant a small garden of rice or maize upon the grave, into which they throw all the effects of the deceased, of the least value to his heirs. Sometimes an oration is pronounced at the funeral of a negro, which sets forth, at the grave, the virtues of the deceased. In some countries they do not bury slaves, but throw their bodies into the fields, as a prey to beasts and birds; in other countries they cover them with earth, without any attendant ceremony.

As to the religion of the Gold coast, it is diversified among a number of sects, proportioned to the number of nations, or rather families, on the coast. All the negroes, however, profess to agree in their belief of one true God, the creator of the world; but his omnipotence is the only attribute of which they have any distinct idea. Some have said, that they conceive of the Deity as partial to the Europeans, and taking pleasure in afflicting them with a thousand evils. Dapper says, that the negroes sacrifice to the devil; but Bosman asserts, that their devotion is wholly paid to the priest, the mediator between them and their divinities. Nothing religious is undertaken without the priest or fetichere, who is consulted on a variety of the most interesting occasions. The practice of exorcism is prevalent among them. All promises of importance, and obligatory oaths, are confirmed by drinking what is called an "obligatory draught;" this is accompanied with an imprecation, that the fetiche may destroy them, if they are unfaithful; but oaths of this nature have been so often violated by nations and individuals, that they are fallen into disrepute. Their public religious ceremonies, on occasion of droughts, floods, barren and unhealthy seasons, &c. are performed by offerings to their idols in groves, which are held peculiarly sacred; and whenever the chiefs of a town or nation assemble, the priests are consulted as to the measures that are most likely to suspend or avert public calamities, and their decrees are solemnly published by a crier. Every negro has his peculiar and appropriate *fetiche*, which he worships on the day of the week when he happened to be born. See FETICHE.

The notions which the negroes entertain of a future state, are very various. Some maintain, that immediately upon the death of any person, he is removed into another world, where he assumes the same character in which he lived on earth, and supports himself by the offerings and sacrifices his friends make after his departure. Bosman affirms, that the greater number of negroes have no idea of future rewards and punishments, annexed to the good or evil actions of this life. Some few, however, he allows to have some gross notions of future judgments, which consist in being wafted away to a famous river, situated in a distant inland country, called "Bosmanque." Here their god interrogates them concerning the life they have led, whether they have religiously kept the holy days dedicated to the fetiche, abstained from all meats, and inviolably kept their oath? those who can answer in the affirmative, are conveyed over the river to a land abounding in every kind of luxury and felicity. Those who have offended in any of the abovementioned particulars, held of principal importance, are plunged by the god into the river, and buried in eternal oblivion. Others believe in a kind of metempsychosis, or transmigration; supposing that they shall be transported to the land of white men, assume that complexion, and be endowed with similar souls; but this doctrine is only maintained by those who think highly of the intellectual faculties of the white men. The inland negroes tell the maritime negroes, that, in a distant interior country, there lives a great fetichere, in a splendid house, who possesses extraordinary powers, and exercises dominion over the elements of nature, and foretels the events of futurity. All persons in his vicinity are examined

amined before him after death, and if the result be unsatisfactory, he kills them a second time; but if their conduct appears to have been pious and exemplary, he furnishes them with a passport to a state of true and perfect felicity. Hence proceeds the deep veneration in which they hold this priest, so that they esteem him little inferior to a god. The negroes, it is said by some, are not ignorant of the devil, whom they regard as a malicious, deceitful being, resembling a white man; but Bosman denies that they pray or sacrifice to him, as most other authors have affirmed. Instead of paying any worship to him, the devil is exorcised out of all their towns at stated festivals, and with abundance of ceremony. The negroes firmly believe the reality of ghosts, spirits, and apparitions; and that they walk up and down the earth, terrifying and beating people, especially the unbelievers. Some have said, that the negroes use circumcision, prayers, and ablutions, and seem to have an indistinct idea of futurity. They believe that good men shall, after death, enjoy happiness, and bad men be doomed to misery; that the former shall live with fine women, upon luxurious diet, and the latter stroll, as vagrants, round the earth, always in motion, and always unhappy. The negroes, in general, have no solemn festivals, besides one at the conclusion of their harvest, which they call a fair, and that already mentioned for exorcising the devil; nor have they any distinction or division of time, except what they have been taught by Europeans. Months and weeks are altogether unknown to them; their method of reckoning being by the shining of the moon, whether it be in the change or in the quarters. Hence they determine their seasons for sowing the different kinds of grain. It is probable, however, that the division of time into weeks and days cannot be of very late date, as all have respectively their peculiar names, which are perfectly familiar even to children. Their sabbath falls on the Tuesday, except at Anté, where it happens on Friday; and it differs from other days in no particular, but that they abstain from fish; all other kinds of food and employments being permitted without any restraint. The negroes of the interior countries divide time into fortunate and unfortunate days; in some countries the great unfortunate days are 19, and the lesser, which differ from the other, 7. Between these intervene 7 unfortunate days, which are a sort of vacation from all occupations and bodily labour. In some countries the lucky days are particularly observed, in others the unlucky ones are no less religiously kept; but the maritime negroes disregard all distinctions, and esteem one day the same with the other.

The government of the negroes is, in general, licentious and irregular: and its forms are divided into five distinct kinds. The first is that of pure monarchy, where the king is despotic; the second is a kind of aristocracy, the chief power being lodged in the hands of the caboceroes or chiefs; the third is vested with those who have acquired weight and influence from their great wealth, which body some have represented as the nobility; the fourth is an absolute democracy, where all are equal with respect to dignity and power, whatever may be their wealth; and the fifth class of persons, rather than government, consists of those slaves, who have been sold by their parents, those who were born slaves, or those whose poverty has reduced them to this unhappy condition. On the Gold coast the crown descends from father to son by right of inheritance, and in default of heirs male, it passes to the nearest of blood; although sometimes a man's wealth in gold and slaves procures him this honour, in prejudice to the lawful heir. The royal government is supported rather by force than by authority; the respect of the people being proportioned to the number of king's slaves and the greatness of his wealth, without which sovereigns find but little respect and submission from their subjects, and are obliged to pay them for the smallest services. But when their kings are rich and powerful, they are elevated by the servile homage of the people above all law and control. Negroe sovereigns are obliged to exercise great liberality, and the first entertainments they give costs a year's revenue. A negroe king is always disposed to aid a neighbouring sovereign with his troops, because the greater part of the subsidy goes into his own pockets. There is nothing peculiar in the education of princes, and it differs little from that of the poorest subjects; so that it is common to see a man taken from the plough-tail to wield a sceptre; and he who was yesterday driving a flock of sheep, shall to-day be at the head of an army. The judges, among the negroes, or the supreme officers of the courts of justice, are chosen from the most considerable persons in respect to wealth and influence. To these belongs the decision of all causes, civil and criminal; and from their decision an appeal lies to the king. War is declared by the negroes either from views of revenge, ambition, or plunder, or as auxiliaries to some injured neighbouring state, or, which is most common, for a subsidy. Many wars are undertaken for the recovery of private debts. When war, from whatever cause it originates, is projected in the king's council, a general assembly of the nobility is summoned, and the matter is deliberately debated. An army is instantly raised, and no time is lost in making an incursion into the enemy's country, and proclaiming war, which is carried on at a small expence. In their engagements, the negroes observe no order or discipline. Their principal arms are muskets or carabines; besides which, they have a kind of swords shaped like chopping-knives; a sort of dart called assagay; and a shield made of twigs and osiers, covered with leather, and sometimes plated on the inside with copper, to ward off the assagays, as well as the blows of the sword. Some few negroes have cannon, but their engineers are so ignorant, that their artillery is of no importance. When the negroes are exhausted with war, which between two despotic sovereigns, who hold their subjects in abject slavery, is generally tedious and bloody, they begin to think of terms of accommodation, and of settling a place of negotiation. This is usually a large plain, on the frontiers of the two contending kingdoms; to this both sovereigns march in full armour, accompanied by a crowd of feticheres, the emblems and mediators of peace. The priests of both nations engage by oath to terminate all hostilities, to live in perfect friendship, and to give pledges of their faith; but the prisoners on either side are considered as the absolute property of the sovereign who possesses them. As soon as these ratifications are exchanged, a loud peal of warlike instruments publishes the general tidings; arms are thrown down on both sides; and the day is closed with festivity.

As the Gold coast is situated near the 5th degree of north latitude, the heat of the climate may be supposed to be extreme; and yet it is more healthy than many voyagers have represented it. During the interval from October to March, the air is very hot, and the other months are tolerable; and through the whole year the extreme heat of the day is moderated by the refreshing and cool sea and land breezes of the evening and morning. It has been observed, that on account of the high mountains that abound on the Gold coast, and the deep vallies that lie between them, the climate is rendered insalubrious by a thick fog, which prevails particularly in marshy grounds and near rivers. From March to October, and in the months of July and August, fogs are very prevalent; and added to the beastly uncleanliness of the negroes themselves, they contribute to render the climate unhealthy, and particularly noxious to strangers.

The

The negroes, however, notwithſtanding all the diſadvantages of their climate and manners, enjoy good health and live to old age.

Boſman divides the ſeaſons on the Gold coaſt into ſummer and winter: the latter admitting of three ſubdiviſions, *viz.* two rainy, two foggy and hazy, and two windy months; but the changes are ſo frequent and irregular, that we cannot lay great ſtreſs on ſuch a diſtribution. This coaſt, however, is ſubject to heavy rains and boiſterous winds; but it derives great benefit from the land and ſea breezes.

On this coaſt the true trade-winds are weſterly, keeping a tract with the ſhore, where it ſtretches eaſtward.

Among the tame animals of the Gold coaſt, the firſt in rank, on account of their utility, are horned cattle, ſuch as bulls, cows, ſheep, and goats, with which Dinkira, Aſſiento, Axim, and all the inland countries abound, though only a few black cattle are brought to the coaſt. It has been obſerved by ſeveral writers, that all the animals are ſpecifically lighter on this coaſt, than in any other part of the globe, a circumſtance which is ſuppoſed to proceed from the nature of their aliment, that, inſtead of firm and ſolid, produces only a ſpongy, looſe, and tough fleſh. The ſheep are much ſmaller than thoſe of Europe, and covered with hair inſtead of wool; nor does their fleſh at all reſemble mutton in its taſte, being dry, lean, and hard. Goats are innumerable, but they are of a very ſmall ſize. Their fleſh, however, is ſweet, fat, and delicate. The horſes produced on the Gold coaſt are of a ſmall ſize; they are ſcarce in the maritime kingdoms, but plentiful in the interior countries. The country likewiſe produces a few aſſes, taller and handſomer than the horſes, and generally preferred for riding. Hogs abound; but their fleſh is lean and hard. Of all animal food, dog's fleſh is moſt valued among the negroes. The dogs of this country, which neither bite nor bark, and which are of all colours, are bred with great care, and driven to market like flocks of ſheep, where they fetch a high price. A cat is much eſteemed among the negroes, ſome of whom eat its fleſh.

Among the wild quadrupeds of this coaſt, we may reckon the elephant, which is of ſomewhat a ſmaller ſize than that of the Eaſt Indies, and which the negroes diſtinguiſh into three kinds, *viz.* the river, the wood, and the mountain elephant; tigers, which are very numerous in almoſt every part of the coaſt; the buffaloe, which is here very ſcarce; the jackall; a ſpecies of wild boar, leſs fierce than that of northern and cold countries, whoſe fleſh is tender, fat, and delicious; deer of all kinds and ſizes; hares, rabbits, and foxes, and a few porcupines. On the Gold coaſt is found a quadruped which the negroes call "potto," the ſluggard; the "berbe," or wine-bibber, ſo called from its fondneſs for palm-wine; the "kokebo" of the negroes; and their "arampo," or man-eater, ſo called becauſe it digs up graves, and prefers human fleſh to all others; and rats and mice, which are the moſt numerous and deſtructive quadrupeds on the Gold coaſt. Lizards, aligators, and cameleons, are alſo found in this country.

The Gold coaſt affords alſo a great variety of birds; its pheaſants are peculiarly beautiful, and it has various others of the feathered tribe, which our limits will not allow us to enumerate. Its reptiles and inſects are alſo very numerous, and of great variety. The coaſt, as well as the lakes and rivers, furniſh great abundance of various kinds of fiſh.

Among the trees, ſhrubs, &c. we may enumerate the palm, which furniſhes the negroes with wine and oil; the cocoa-tree; ſweet and ſour oranges, and lime trees; the papay-tree; the banana-tree; and vines. In a word, the Gold coaſt affords fruit-trees of all ſorts, and wood for all purpoſes.

As to the grain of the coaſt, it conſiſts of the great and ſmall milhio, ſuppoſed to be the Turkiſh wheat, which affords two crops in the year; and rice, which is yielded in great abundance. Its other vegetables are yams, potatoes, and beans, ſome of which are peculiar to the country. It furniſhes alſo the Guinea pepper, Spaniſh pepper or pimento, cardamoms, and a number of fruits, and grains, common to almoſt all countries.

Tobacco is alſo produced in great plenty on the Gold coaſt, to the uſe of which the negroes are much addicted. We ſhall cloſe this detail with obſerving, that the Gold coaſt furniſhes a vaſt quantity of ſalt.

Of the inland country, little more is known, than that it conſiſts of three extenſive kingdoms, called Aſſiantee or Shantee, Akim, and Aquamboe, each of which ſupplies the maritime ſtates with a great number of ſlaves, whom they ſell to the Europeans. In the Britiſh Weſt Indies moſt of the negroes purchaſed on the Gold coaſt, are known by the general appellation of Koromantees, from *Koromantyn*, which ſee. The number of ſlaves furniſhed of late years by the Gold coaſt has been eſtimated at 10,000.

Coast, *Grain*, *Pepper*, or *Malaguetta*, is the moſt weſtern diviſion or province of Guinea, and bounded by Nigritia on the north; the Ivory coaſt on the eaſt; and on the ſouth and weſt by the ocean. It is contained between the Rio Seſtos and Grova, a village two or three miles from cape Palmas, extending for a ſpace of 55 miles along the ſhore. But if it commence at the river Sanguin, and ſtretch to Cape Palmas, its limits will be enlarged about 60 miles. Within theſe frontiers are the towns and villages of Seſtos, or Seſtro, W. of the river Sanguin, Bottowa, or Battaway, Seno, Seſtro Krou or Kro, Wappo, Bado, Great Seſtro, Little Seſtro, Goyava, Garaway, &c. &c. The chief rivers are the Rio de Seſtro, the Rio de St. Paul, and the river de Sierra Leona. The climate on this coaſt is materially affected by the exhalations raiſed by the ſun from the rivers and ſea-coaſt, which are ſaid to occaſion putrid fever, almoſt always fatal to Europeans. The productions of the earth are peaſe, beans, gourds, lemons, oranges, and bananas. The palm-wine and dates of this country are excellent. Cows, hogs, ſheep, and goats abound; but that which conſtitutes the chief wealth of the Grain coaſt is the abundance of Guinea pepper which it produces. But the principal commerce of the Grain coaſt conſiſts in ivory and ſlaves. As to the manners of the natives, they are not chargeable with any kind of intemperance; but they allow their women, who are well-formed and handſome in their perſons and features, every kind of intercourſe with Europeans, and ſome of them are guilty of the moſt infamous proſtitution. Theft is common among them, as it is among all negroes. Their language is altogether unintelligible not only to Europeans, but to their neareſt neighbours; and as they have no interpreters their commercial tranſactions are carried on by ſigns and tokens. Among theſe people there are many excellent mechanics, and particularly ſmiths, who underſtand the art of tempering ſteel, and making arms: their ſhipwrights are alſo expert in the ſtructure of canoes. They have likewiſe derived from experience many improvements in huſbandry, eſpecially ſuch as regard the culture of rice, millet, and Guinea pepper, which are the chief articles of their ſubſiſtence and commerce. Their government is arbitrary and deſpotic; and their ſovereign, who on all occaſions appears among them with pomp and magnificence, is regarded with a kind of awe, as if he were a ſuperior being. Although

though ignorance attaches them to the rites of paganiſm, natural reaſon ſuggeſts to them ſome ideas of a future ſtate, as we may infer from the ceremonies performed in relation to the ſouls of the deceaſed, which they hope to find in a ſtate of happineſs. They welcome the new moon with ſongs, dances, and various kinds of diverſion; and their ſuperſtitious regard for ſorceries is extreme. For a further account of theſe people, we refer to the article SESTOS. The months moſt favourable to trade on this coaſt are February, March, and April; and ſmall veſſels are more convenient than large ſhips, as they are better adapted for entering the rivers and ſailing up the country. The ſouth-ſouth-eaſt winds begin to blow on this coaſt in the month of May, and they are conſtantly attended with heavy rains and ternadoes, extremely dangerous to ſhipping, with thunder and lightning that are terrible.

COAST, *Ivory*, *Tooth*, or *Quaqua*, ſo called from the elephants' teeth which are found here, is a province of Guinea, bounded by Nigritia on the north; by the Gold coaſt on the eaſt; by the ocean on the ſouth; and by the Malaguetta, or Grain coaſt on the weſt. Geographers and ſeamen are much divided in their ſentiments concerning the extent and limits of this coaſt: ſome confining it between the Rio Suero da Coſta, where the Gold coaſt begins, and Grova, about three miles from Cape Palmas; whilſt others ſtretch its boundaries from Cape Palmas to Cape Tres Puntas, the whole of that ſhore being known to mariners under the appellation of the Tooth coaſt. However, the moſt preciſe and accurate limits are contained within Cape Apollonia to the eaſt, and Cape Palmas to the weſt. The principal towns of the Ivory coaſt are Grova or Grua, Great Tabo, Little Tabo, Great Drewin, Batrou, Laho, Apollonia, and Vallo, each of which ſtands at the mouth of the river, whence it reſpectively derives its name. As for the interior country, it is but little known; the natives refuſing the Europeans leave to eſtabliſh ſettlements, or even to trade among them, except by means of the coaſt-negroes, and this they allow with the moſt circumſpect caution. The ſame commodities are found here as in the other provinces of Guinea; *viz.* gold, ivory, and ſlaves. Grova ſtands three miles E. of Cape Palmas; Great Tabo, 30 miles from Grova, eaſt; Little Tabo four miles farther eaſt; thence to Great Drewin 11 miles, thence to Batrou 19 miles, to Laho 7, and from thence to Cape Apollonia 20 miles:—the whole amounting to 94 miles. The river St. Andrew on this coaſt is a fine, deep ſtream, increaſed near its mouth by the influx of another river, both which unite in forming a large road. The entrance is ſurrounded with lofty trees, beautiful verdant meadows, and rich fields of great extent. About 500 paces from the mouth of the river a peninſula runs a great way into the ſea, joined to the continent by a ſlender neck of land, about 5 or 6 fathoms broad. The whole peninſula is a high level rock; having a platform 400 feet in circumference, and commanding the whole neighbouring country. At the foot of a little eminence, N. of the neck of land, there is a fine freſh water ſpring, capable of ſupplying a large garriſon, and of being ſecured by the cannon of the fort. The land-marks here are ſo diſtinct that it is impoſſible for ſhips to miſtake them. They conſiſt of lofty, thick, and ſhady trees, with three or four large villages, within leſs than half a mile of each other. The fields and meadows near the mouth of the river are fertilized by meandering ſtreams, and are thus rendered fit for producing every ſpecies of grain, fruits, and roots; but eſpecially maize, millet, rice, peaſe, yams, and melons. Here alſo grow oranges, limes, cocoa-nut trees, and citrons, forming large groves; and here alſo the ſugar-cane, and a thouſand other plants, which ſpring up without cultivation are abandoned to the ravages of the elephant, and as haunts for wild beaſts. Whatever the Gold coaſt produces is alſo found here, in greater abundance and perfection; and, indeed, the fruits and vegetables of the warmer climates ſeem to be all united on the Ivory coaſt. As to the manners of the natives in this diſtrict, the men wear a looſe dreſs which hangs down to the knees, and the women, a narrow cloth round their waiſts. Many of them are naked. The richer of both ſexes have a paan of fine cloth, and the men wear poniards, or long knives by their ſides. The women are ſmall, but neatly proportioned. Their features are regular, their eyes lively, and their teeth white, ſmall, and even. The men are likewiſe well-formed; and are not deficient, either in courage or underſtanding. They are very fond of bracelets of iron and ivory, mounted with little bells, which they put round their arms and the ſmall of each leg. Theſe bells inſpire them with additional joy in dancing, to which they are much addicted, as well as all the negroes. Eaſt of the river St. Andrew are at leaſt a dozen of craggy, rugged mountains, ſtretching three or four miles along the coaſt; but the intermediate fields, well watered by nearly twenty rivulets, are rich and fruitful: ſo that if the inhabitants were ſomewhat more civilized, no country on earth bids fairer for a profitable commerce. The elephants are of an enormous ſize: ſlaves and gold are alſo very plentiful.

From the Rio de Suero da Coſta to Cape Apollonia, the coaſt is low and even, extending itſelf 12 miles towards the eaſt, bordered with large trees, and covered with villages, the chief of which are Boquun, Iſſini Peguena, Great Iſſini, Albiani, Jabo, and Akammina. Between Boquun, which ſtands at a ſmall diſtance from the ſhore, near the mouth of the river Da Coſta, ſurrounded by woods, and pleaſantly ſituated, and Akammina, ſeated on a riſing ground half a mile W. of Cape Apollonia, and commanding an extenſive ſea and land proſpect, the interior country is high, rugged, and mountainous, but affording ſome fine gold, ivory, and a few ſlaves. Near Cape Apollonia is the kingdom of *Gu[illegible]re*, which ſee. The whole coaſt from Cape Palmas to Cape Apollonia, a few capes excepted, appears ſo low, but ſo equal and ſtrait, that places cannot be eaſily diſtinguiſhed, and, beſides the capes, the only diſtinct land marks are the heights and mountains about Drewin. The landing is dangerous, on account of high ſurfs and ſwelling waves; and the negroes alone are ſo acquainted with the coaſt, and ſo reſolute, as to encounter its dangers in their little canoes; which are employed in loading and unloading the ſhipping. Round Cape Apollonia there are large tracts of fallow land, in which the negroes ſow Indian corn. The complexion of the natives is ſo black, that it has been compared to the fineſt jet; in their diſpoſition they are lively and enterpriſing, and in commerce indefatigable. Their huts are neater and cleaner than thoſe of their neighbours, and their dreſs more elegant, being ſet off with ornaments of gold, ivory, and cowries. The hair or wool of their heads is divided into innumerable ſmall treſſes, which they adorn with fragments of oyſter ſhells and other ſhining baubles. On the left cheek they have a ſcar, of the figure of a poniard, and the reſt of the body is often marked in the ſame manner, to denote the warlike diſpoſition of the perſon; this cuſtom is very ancient, and ſerves to diſtinguiſh the inland from the maritime natives; the former of whom are often reduced to ſlavery by the latter, and ſold as ſlaves. From Cape Apollonia to the river Mankaw, where the province of Axim, the firſt diviſion of the Gold coaſt, begins, are two or three fine villages. From hence to Axim, the ſhore takes its courſe S.S.E., and near the village of Boggio the river

Mankaw empties itself into the sea, at the mouth of which the negroes find a considerable quantity of gold.

Every country within the limits of the Ivory coast is fruitful in rice, pease, beans, gooseberries, citrons, oranges, and cocoa nuts; and sugar-canes might also be cultivated here to great advantage. Upon the whole, the Ivory coast is reckoned one of the finest divisions of Guinea; the prospect of the mountains and vallies, filled with villages, is delightful; most of these little towns being surrounded with lofty palms and cocoa trees. The soil of the high land is a reddish earth, which, with the perpetual verdure of the trees, forms an agreeable mixture of colours. Cotton and indigo are the spontaneous growth of the districts of Great Drewin and St. Andrew, which are indeed the richest of the whole. Palm-wine and oil are plentiful; together with a species of fruit, growing on a sort of palm-tree, called by the natives "tombo," or bourbon." All sorts of tame animals, sheep, cows, goats, and hogs are very numerous and cheap: and the coast supplies great abundance and variety of fish.

The natives, in general, are above the common stature, well-limbed and well-proportioned, though their features on the first glance are hideous: and yet they are deemed the most rational, civilized, and polished people in Guinea; applying this character to the natives of the Quaqua coast, or from the river Drewin to Cape Apollonia; for as to the others, authors concur in representing them as the most barbarous, cruel, and savage of all nations. Their diet is coarse and indelicate. Black soup is a favourite dish all over Guinea, both among Europeans and negroes. The Europeans make it of flesh or fowl, with pepper, vinegar, salt, and some sweet herbs peculiar to the country; but the negroes add fish, ocra, which is a viscous vegetable substance well known in our West Indian islands, where it is used to thicken soup, and palm-oil. The men are fond of a great quantity of hair, with which they are supplied by the women, who cut off their own for this purpose. Some of the women, who wear their hair, adorn it with little plates of pure gold. Their form of salutation they have in common with all negroes; which is that of laying hold of the fingers, making them crack, and repeating the word "quaqua" several times, in a low voice. It is a constant rule, that the son follows the profession of his father. In the mechanic arts they are unskilled, insomuch that a common door-lock is reckoned among them as a very great curiosity; a watch still further increases their admiration; and making paper to speak, as they express it, is a perfect miracle. Their religion, like that of the inhabitants of the Gold coast, is founded in ignorance and superstition. They revere their princes and priests, under a persuasion that magic and sorcery are qualities inseparable from majesty and priesthood. The usual trade carried on with the inhabitants of this country, who are generally very timid and jealous in their intercourse and commercial transactions with Europeans, consists of cotton cloths, ivory, gold, and slaves. From the river Babas to the Rio de Suero da Costa, the country produces great abundance of good cotton, which the negroes of the interior country manufacture with great industry, and which they sell to the inhabitants of the Gold coast, and to those who fetch it from it central parts of Africa. The Quaqua negroes manufacture a kind of plant, resembling hemp, into a strong cloth, to which they give a beautiful colour, and some pretty flowers and designs, that indicate them to be no bad artists in this way. They have also a considerable trade in salt, with their inland neighbours. All the countries behind Quaqua furnish a large store of the most beautiful ivory in the world, which they sell principally to the English and Dutch. They obtain likewise from the mountains a considerable quantity of gold. The European commodities, which the negroes accept most readily in exchange for their own, are of much the same nature as in other parts of Guinea. When the natives of this coast trade with any European ship, they let fall a few drops of water into their eyes, by which symbol, equivalent to a kind of oath, they intimate that they would sooner lose their eye-sight than cheat those with whom they trade. They are no less averse to drunkenness than to fraud; for though their country abounds with palm-trees they drink no palm-wine, but only a certain small liquor which they mix with water. Although this country be divided into a variety of petty states and kingdoms, yet they have scarcely any separate interests: for among themselves war seldom happens; and, consequently, the slave trade here bears but a small proportion to that traffick on the Gold and Slave coasts.

Coast, *Slave*, is generally included by European navigators under the limits of the kingdom of Benin. It is bounded by the Rio de Lagos in this kingdom, and extends to the Rio da Volta, the boundary on this side of the Gold coast. The coast is generally distinguished by the appellation of Great Benin. (See Benin.) From port Douarre it extends towards the south of Cape Formosa; then turning eastward to Rio del Rey, and again inclining to the south of Cape Gonsalvo, towards the equator, it forms the gulf of Guinea. Thus, in its whole length, it measures about 350 leagues in a curve line, or arc of a circle. The Slave coast comprehends the coasts and kingdoms of Coto or Koto, Popo, Whidah, and Ardrah: which see respectively.

Coast, *Windward*, an appellation commonly given to that part of Africa, which extends from Cape Roxo, or Rouge, to Cape Apollonia. The European settlements on this coast, except a small English factory in the river Sierra Leone, are chiefly those of the Portuguese. The negroes obtained from them, as well as from the English factory, have been called "Mandingoes," though not with strict propriety, as many different languages are spoken on the coast between Senegal and Apollonia.

Coast, *Cape*, the chief settlement of the English on the Gold coast in Africa: the ancient Portuguese appellation is "Cabo Corso." This Cape is formed by an angular point, washed on the south and east by the sea, upon which stands the English fort, about 9 miles from Elmina. Here the Portuguese settled in 1610, and built the citadel of Cape Coast, upon a large rock that projects into the sea. Some few years afterwards they were dislodged by the Dutch, to whom this place owes its principal strength. In 1664, it was demolished by admiral Holmes; and in 1665, De Ruyter, the famous Dutch admiral, had orders from the states to retaliate the injuries committed by the English. But though, with a squadron of 13 men of war, he attacked all the settlements of this nation along the coast, ruined all the factories, and took, burnt, and sunk all the shipping of the English company, he was frustrated in his attempts upon this fort, which had not at that time recovered the damage which it had sustained in the expedition of Holmes. The treaty of Breda having confirmed Cape Coast to the English, and the king granting a new charter in 1672, the directors applied all their attention to fortifying and rendering commodious this, their chief possession. The walls are high and thick, especially on the land side, built partly of stone, but chiefly of brick, which the English made at a small distance. To the height and strength of its walls the fort owes its chief security, and the neighbouring negroes dependent on the company, derive from them a protection against the incursions of the Fantins. The interior parade, raised 20 feet above the surface of the work, forms a quadrangular space, cooled by the gentle refreshing

freshing sea-breezes to which it lies open, and pleasantly situated, having queen Anne's point, and all the shipping in the road of Anamaboa in view. The platform is defended by pieces of artillery, which command the road and its entrance. The fort has four bastions, mounted with cannon; other pieces are placed on the battlements, and others on the wall towards Tabara for the purpose of keeping the negroes in awe; towards the sea, the perspective of Cape Coast is beautiful and regular; the fortifications are well conceived, and the advantages of natural situation are aided by art. Cape Coast, however, has inconveniences, among which we may reckon some neighbouring hills, by means of which an enemy might without difficulty embarrass and annoy the fort. The soldiers are lodged in the best barracks of any on the coast of Guinea. The governor's apartments communicate with the chapel: near the gate is a prison for criminals, and beneath the platform, a large vault is cut in the rock for the confinement of slaves. The presidency of Cape Coast is lodged in the hands of a single person, appointed by the directors of the African trade; and the usual commerce consists chiefly in gold dust and slaves. The company's gardens occupy a space of no less than 8 miles in circumference, being surrounded by trees; and the soil is every where so fertile, that it produces every sort of fruit commonly found in the warmer climates, as lemons, oranges, citrons, guavas, mangoes, plantains, bananas, pine-apples, tamarinds, cucumbers, water-melons, cocoa-nuts, and every kind of sallad and roots.

In the neighbourhood of Cape Coast, the English have built two forts, the one called "Philips's tower," and the other "Fort Loyal," or "queen Anne's fort," each of them being three-quarters of a mile distant from the Cape Coast. The first stands on an eminence on the side of the garden S. E. of the fort. The second is situated near the village of Manfro, upon a hill called Danistein, where Fredericsburgh formerly stood. Cape Coast is in N. lat. 4° 58′. E. long. 1°.

COASTING, that sort of navigation, wherein the places, sailed to and from, are not far distant; so that a ship may sail in sight of the land, or within sounding, between them. Such are the voyages on the Narrow, or British seas, between England, Holland, and France; also those about the British seas, and in the Mediterranean, &c.

For the performance of this navigation, there is only required good knowledge of the land, of the time and direction of the tide, of the reigning winds, of the roads and havens, the use of the compass, and of the lead, or sounding-line.

[illegible] Sail[illegible]

[illegible]. See Pilot.

Coasting, in *Agriculture*, &c. denotes the transplanting of a tree, and placing it in the same situation, with respect to east, west, north, &c. as it stood before.

COAT, in *Anatomy*. See Tunica and Eye.

Coat *of Arms*, in *Heraldry*, a surcoat reaching to the waist, open at the sides, and ornamented with armorial bearings, worn by the ancient knights in times of war, or at tournaments over their armour, being the principal characteristic by which they were distinguished from one another, the [illegible] being covered with the helmet.

During the period of five centuries after the conquest, the variation in the mode of exhibiting coat-armour was very trivial.

The Norman in the field being closely invested in armour, which exactly fitted his shape, threw over it an ornamented surcoat without sleeves, at first loose; but during the successive reigns of the three first Edwards, it was confined to the body in narrow folds. After that, the mixed armour (composed of mail and plates) became common, and the steel boddice was gilt and otherwise ornamented. This armour did not, however, long continue in fashion, but was succeeded by tabards of arms, larger than the original surcoat and made of the richest silk stuffs, sumptuously embroidered, which afterward became the dress worn by the nobility and gentry, till the commencement of the sixteenth century: since that time they have been continued only as the state dress of the officers of arms. See *Plate* of *Heraldry*.

Coat *of Mail*, in French *cotte de mailles*, in *Military Language*, armour made of scales or iron rings connected together net-wise.

Coat, in a *Ship*, a piece of tarred canvas put about that part of the masts, or bowsprit, which joins to the deck, or lies over the stem of a ship. They are also put about the pumps at the decks, that no water may go down there; and they are also used at the rudder's head.

Coat likewise denotes the materials with which the ship's sides and masts are varnished, to preserve them, as tar, &c.

COATI, in *Zoology*, the name given by Seba to the little ant-eater, Myrmecophaga *didactyla*.

Coati is a name also assigned by Marcgrave to the Brasilian weesel, the animal described in the Transactions of the French Academy under that of *Coati mondi*, Viverra Nasua of Gmelin.

Coati, of Ray's quadrupeds, is the animal commonly called the racoon, Ursus Lotor of Schreber, and Gmelin.

COATING, in its general sense, denotes the covering of a body, or the spreading of one substance over another; and this is practised, with various views, in civil economy, in the arts, and in some scientific branches of knowledge. Thus, human beings are covered with various garments, both for defence and for ornament; houses, vessels, and most works of wood, are covered with paint, or pitch, or lead, or copper, or other matter, for the same purposes; the baser metals are covered with the richer, silver is coated with gold, copper with gold or silver in ornamental works; iron or copper is coated with tin for culinary purposes, in order to prevent the rusting of the former, and the noxious effects of the latter; and so forth. See the practical methods of performing these operations under the articles Painting, Plastering, Gilding, Silvering, Tinning, &c.

Coating, in *Chemistry*, is used principally for the purpose of defending certain vessels from the immediate action of fire; thus, glass retorts and the inside of some furnaces are coated with various compositions. See Lorication, and Luting.

Coating, in *Electricity*, means the covering of electric bodies with conductors, or the latter with the former, or, lastly, electrics with other electrics. Electrics are coated with conductors, for the purpose of communicating to, or removing from, their surfaces, the electric fluid in an easy and expeditious manner; otherwise an electric body, on account of its non-conducting property, cannot be electrified deprived of the electric fluid, without touching almost every point of its surface with an electrified or other body. This coating generally consists of tin-foil, sheet-lead, gilt paper, gold leaf, silver leaf, or other metallic body, either in the form of a thin extended lamina, or in small grains, such as brass filings, and leaden shot. The coating may be fastened to the surface of the electric by means of paste, glue, wax, or other adhesive matter. In lining Leyden phials, care should be had not to fasten the coating (if it consists of brass filings or gold leaf) with varnish; for this is apt to take fire on making the discharge. But in some cases the metallic coating is merely laid upon the electric; for instance, in certain experiments, a piece of tin-foil, or a brass plate, is laid

laid upon a pane of glafs, fo that after having charged the glafs, the coating may be eafily fhook off; and a Leyden phial is, fometimes, partly filled with leaden fhot, which performs the office of an inner coating, and may be eafily poured out of it. Alfo, when two extended parallel metallic furfaces are placed at the diftance of about an inch or two from each other, the intervening ftratum of air (being an electric) is faid to be coated, and may be charged and difcharged like a Leyden phial. When the electric is of a very fufible nature, fuch as fulphur, fhell-lac, fealing-wax, &c. a cafe of it may be coated by pouring it melted upon a metallic plate, or in a cup, which is required in certain experiments. See ELECTRICITY, ELECTROPHORUS, and LEYDEN *phial*.

In certain cafes conductors are coated with electrics, either partially or entirely, for the purpofe of preventing the abforption or diffipation of the electric fluid from their furfaces. This is done with varnifh, or more effectually with fealing-wax, the latter of which, when the fhape and fize of the conductor allows it, may be eafily performed by warming the conductor to a certain degree, which is indicated by actual trial, and then rubbing a ftick of fealing-wax over its furface.

Laftly, the coating of electrics with other electrics, is principally, if not exclufively, practifed with articles of glafs; for, fince moifture eafily adheres to the furface of glafs, the infulating quality of the latter is thereby greatly diminifhed and often annihilated; hence the glafs feet of infulating ftools, the glafs handles of directors, the pillars of fome electrical machines, &c. are generally covered with fome other electric fubftance of a refinous quality, which is not apt to attract moifture. The fubftances principally ufed for this purpofe are fealing-wax and varnifh. When the glafs article is fufficiently fmall, the beft way of covering it with fealing-wax is, to heat the former, and then to rub a ftick of fealing-wax over it, fo as to form an equal coat of the wax over the furface of the glafs; and this is, by far, the beft mode of obtaining the defired object; but when the piece of glafs is too large, then the fealing-wax muft be diffolved in fpirit of wine, and muft afterwards be fpread over the glafs with an hair pencil; having previoufly wiped the glafs perfectly clean and dry. In this cafe, however, care muft be had to ufe the beft rectified fpirit of wine, or alcohol; for if impure fpirits be ufed, the folution of fealing-wax, when fpread upon the glafs, will infulate very imperfectly, or even not at all. Of the diffolved fealing-wax you may lay two, three, or more, coats upon the glafs, always allowing one coat to become perfectly dry, before the next is put on.

With refpect to the ufe of varnifh, it muft be obferved, that very few of the common varnifhes will anfwer this purpofe in any tolerable degree. This is one, however, which, when properly made, and carefully applied, anfwers as well as the fealing-wax coating. This varnifh, which was long kept a fecret, is made in the following manner: Take half a pint of linfeed-oil, one ounce of faccharum faturni, and one ounce and a half of litharge. Set them in an iron veffel to boil over a fmall charcoal fire (*viz.* fuch as is barely fufficient for the purpofe), ftirring the materials frequently with an iron fpatula or an old knife. As foon as thefe ingredients are incorporated, add one ounce and a half of prepared amber, and let it continue to boil, ftirring the materials frequently, until you find upon trial, that a drop of the liquor, placed between two knife blades, ftretches like thick glue, or like turpentine. When this takes place, remove the veffel from the fire, fuffer it to cool a little, and then mix fpirit of turpentine with it, ftirring the whole together, which will thin it; but take care not to render it too thin; for by keeping, in a few days, it will of itfelf grow thinner. Laftly, keep it in bottles for ufe. *N. B.* The iron veffel muft be much larger than the quantity of ingredients might require, and it muft be furnifhed with a handle, becaufe the oil, &c. in boiling, is apt to fwell and will run over, if the veffel be not quickly removed from the fire. The amber is prepared, firft, by powdering it; fecondly, by melting, or rather charring it, in a fhovel over the fire; and, laftly, powdering it again in a mortar. This varnifh is ufed in the fame manner as the above mentioned folution of fealing-wax; but you need not lay on more than one coat of it, or, at moft, two.

COATZACUALCO, in *Geography*, a navigable river of Mexico, or New Spain, which difcharges itfelf into the gulf of Mexico, near the country of Onohualco.

COAVO, or CUAVO, a river of Africa, which runs into the Indian fea. S. lat. 8° 40′. E. long. 38°.

COB-*Nut*. See HAZLE.

COBA, or COBE, in *Ancient Geography*, a trading town or emporium of Ethiopia; feated on the Avalite gulph, according to Ptolemy.

COBÆA, in *Botany* (fo named by Cavanilles, in memory of father Barnabas Cobo, a Jefuit, who, after living forty-five years in North and South America, compofed a natural hiftory of the new world, ftill extant, but never publifhed), Vent. v. ii. p. 401. Cav. Ic. 16, 17.

Gen. Ch. *Cal.* pentagonous, one-leafed, with five expanding fegments. *Cor.* monopetalous, funnel-fhaped; tube very long, gradually dilated; border campanulate, five-cleft; fegments open, flightly crenated. *Stam.* Filaments adhering to the lower part of the tube, declining,; anthers oblong, verfatile, at firft fhorter than the corolla, afterwards longer, and becoming twifted in a fingular manner. *Pift.* Germ furrounded at its bafe with a pentagonous glandular rim or nectary; ftyle longer than the ftamens; ftigmas three or five, reflected. *Capfule* from three to five-celled. *Seeds* numerous, imbricated.

Sp. C. *fcandens*, Cav. Icon. tab. 16, 17. Bot. Mag. 851. (Cobbea, Bot. Rep. 342.) An elegant climber. *Leaves* alternate, equally pinnated, terminated by a dichotomous tendril; leaflets egg-fhaped, acute. *Flowers* at firft green, finally changing to a bright violet, large, axillary, folitary. A native of Mexico, where it is called yedra, morada, or violet ivy. It grows with aftonifhing rapidity, and is eafily propagated by cuttings. Firft raifed by Cavanilles in the royal garden at Madrid, and fince both in France and England

COBALT, *Kobolt*, Germ. in *Mineralogy*. Cobalt is a metal of a white colour, inclining to bluifh, or fteel-grey; when tarnifhed, acquiring a reddifh tinge; its fracture is compact, fine-grained, and uneven. Its fpecific gravity is 8.53. It is attracted by the magnet, and is itfelf capable of polarity. At a common temperature it is brittle, and eafily reduced to powder, but when red hot may be flightly extended under the hammer. It requires for its fufion nearly the fame heat as caft iron does. When in the ftate of oxyd it tinges the faline vitreous fluxes of a deep blue. It is foluble in nitro-muriatic acid, and the folution forms a blue-green fympathetic ink.

§ 1. *Ores of Cobalt.*

Cobalt occurs, 1ft, mineralized by arfenic; 2d, as an oxyd; 3d, combined with arfenic acid; 4th, combined with fulphuric acid.

Sp. I. *Arfenical Cobalt.*

Cobalt is never found pure in the metallic ftate, but is always

always alloyed with arſenic, and often beſides contains iron and ſulphur, and ſometimes nickel, biſmuth, and ſilver.

Of the ſub-ſpecies only the cryſtallized (3d ſub-ſpecies) has been analyzed, and both by Klaproth and Taſſaert. The following are the reſults. Klaproth obtained

Cobalt -	44.
Arſenic -	55.5
Sulphur -	0.5
	100.0

Taſſaert obtained

Cobalt -	36.66
Arſenic -	49.
Iron -	5.66
Sulphur -	6 5
	[illegible]
Loſs -	[illegible]
	[illegible]

Similar differences are obſerved between the analyſes of this variety by other chemiſts, ſo that it may be conſidered as allowing conſiderable range both in the proportion and nature of its conſtituent parts, without materially affecting its cryſtallization. It appears, however, from Hauy, that when the cryſtals diſplay a lamellar fracture, they contain a notable proportion of ſulphur and iron. We ſhall follow Brochant's arrangement of the ſub-ſpecies.

1. Sub-ſpecies. White cobalt. *Weiſſer Speiſkobolt. Cobalt blanc*, (ſpecies 2 of Kirwan and Hauy).

The colour of this mineral, when recently broken, is tin-white, but its ſurface is generally yellowiſh, bluiſh, greyiſh, or irideſcent, like ſteel that has been heated. It occurs in maſs, diſſeminated, kidney-ſhaped, and rarely in minute quadrangular tables, or imperfect cubes and octohedrons. Their external luſtre is ſlight, but internally is brilliant and metallic. Its fracture is fine-grained and uneven: when broken, it flies into ſharp-edged irregular fragments: when in maſs, it contains fine-grained granular diſtinct concretions. It requires a poliſh by friction, is brittle and hard: when expoſed to the blow-pipe, white cobalt melts with great eaſe, giving out a white vapour, and a ſtrong arſenical odour, and a white brittle bead of metal remains, which gives a blue colour to glaſs of borax, when melted with it.

It is found in Norway, at Tunaberg in Sweden, Annaberg in Saxony, and alſo, rarely, in Swabia and Stiria. In Saxony and Norway, it is contained in beds of micaceous ſchiſtus, accompanied by the red earthy cobalt, quartz, hornblende, and pyrites.

2. Sub-ſpecies. Dull-grey cobalt. *Grauer Speiſkobolt. Cobalt gris*, (ſp. 1. of Kirwan and Hauy.)

The colour of this mineral is a clear ſteel-grey, but by expoſure to the air it acquires an irideſcent tarniſh. It occurs in maſs or diſſeminated, ſometimes in kidney-ſhaped or cluſtered maſſes, and very rarely in ſpecular laminæ. Its external luſtre is very feeble, but internally it exhibits a bright metallic luſtre. Its fracture is compact, generally even, but ſometimes paſſing into flat-conchoidal; its grain is remarkably fine and cloſe. Its fragments are ſharp-edged, indeterminate. It is not ſo hard as the preceding, and is leſs brittle. Its ſpecific gravity varies from 4.3 to 5.3, or even 5.5. It gives a bluiſh-grey metallic ſtreak.

When expoſed by itſelf to the blow-pipe, it gives out an arſenical vapour and ſmell; but ſeldom fuſes: when treated in the ſame way with borax it gives the flux a blue colour, and is reduced to a metallic globule.

A ſpecimen from Cornwall was analyſed by Klaproth, who procured from it about 20 per cent. of cobalt; 24 of iron, and 33 of arſenic, the remainder conſiſting partly of biſmuth and ſulphur, together with earthy matter. Some varieties have alſo been found to contain nickel and ſilver. It is found in Saxony, Bohemia, Swabia, and Hungary; alſo in Stiria, France, Norway, and Cornwall.

3. Sub-ſpecies. Bright white cobalt. *Glanz Kobolt. Cobalt eclatante.*

The colour of this mineral is tin-white, but tarniſhes to greyiſh, whitiſh, or irideſcent. It is found in maſs, diſſeminated or inveſting, or of particular ſhapes, as cluſtered, kidney-ſhaped, globular, or cryſtallized in cubes or octohedrons. The cryſtals are middling-ſized or ſmall, their ſurface is commonly ſmooth and brilliant, and marked with ſtriæ on the ſides of the primitive cube. The fracture of the cryſtals is lamellar, that of the other varieties is fine-grained, uneven, or radiated. When in maſs it preſents granular, or lamellar, or teſtaceous diſtinct, concretions. Its hardneſs is ſomewhat inferior to the preceding ſub-ſpecies: when pulverized, it is of a ſteel-grey colour. Sp. gr. 6.2 It is brittle, and eaſily frangible.

Before the blow-pipe, it burns with a faint white flame, diſengaging arſenical vapours; it then becomes black, is attractable by the magnet, and is, with the utmoſt difficulty, reduced to a metallic globule. It often contains as much as 50 per cent. of reguline cobalt.

This is the commoneſt of all the ores of cobalt: it occurs for the moſt part in primitive mountains, together with the other ſpecies of cobalt ore, with vitreous, red, and native ſilver, with arſenical and cupreous pyrites, &c. It is met with in various parts of Germany; alſo in Sweden, Norway, Stiria, and Cornwall.

Sp. II. *Earthy Cobalt.*

Of this there are the four following varieties:

Var. 1. Friable black cobalt. *Schwarzer Kobolt muhn. Cobalt terreux noir friable.*

The colour of this is black, bluiſh, browniſh, or greyiſh black. It is without luſtre, has a looſe earthy conſiſtence, is friable and meagre, ſtains the fingers in a ſlight degree, and gives a brightiſh ſtreak. It is ſoluble in muriatic acid; tinges borax blue, and very rarely ſhews any indications of ſulphur or arſenic, when treated by the blow-pipe.

Var. 2. Indurated black cobalt. *Verhärteter ſchwarzer kobolt. Cobalt terreux noir endurci.*

In colour it reſembles the preceding, except that it is ſometimes of a dark greeniſh black. It occurs maſſive, diſſeminating, inveſting, kidney-ſhaped, cluſtered, or in veins. It is dull, but takes a poliſh by friction. Its fracture is earthy and compact, paſſing into flat-conchoidal. It poſſeſſes a moderate degree of hardneſs. Sp. gr. from 2. to 4. With nitric acid it gives a red ſolution, and a bluiſh-green one, with muriatic acid. It has not been accurately analyſed, but conſiſts of oxyd of cobalt, with a ſmall variable proportion of arſenic and ſulphur mixed with vitreous ſilver ore, oxyd of iron, and clay.

This, and the preceding variety, are always found together; but the indurated is by much the moſt rare. It is found in Saxony, Thuringia, Swabia, and the Tyrol.

Var. 3. Yellow cobalt. *Gelber erdkobolt. Cobalt terreux jaune.*

Its colour is that of faded ſtraw, paſſing into yellowiſh white, and often ſtreaked with brick-red. It is found in maſs, diſſeminated or inveſting. It is without luſtre, has a fine-

fine-grained earthy fracture, gives an unctuous ftreak, and is foft and friable.

It is infufible *per fe*, gives a feeble, arfenical odour, and communicates a deep blue tinge to borax: but when mixed with iron, as it often is, the colour is greenifh.

This is one of the rareft of the ores of cobalt. It has hitherto been found only in Thuringia, Wirtemberg, and Dauphiné.

Var. 4. Brown cobalt. *Brauner erdkobolt. Cobalt terreux brun.*

Its colour is a clear liver-brown, paffing into grey, yellow, and black. It occurs in mafs or diffeminated; it is dull, but acquires a greafy luftre by friction. Its fracture is fine-grained, earthy. It is eafily broken, being almoft friable. It has been analyfed, but appears to be the connecting link between the fecond and third varieties. When thrown on burning coals, it generally gives out an arfenical odour.

Sp. III. *Red Cobalt.*

Of this there are two varieties.

Var. 1. Cryftallized. *Koboltblute. Fleurs de Cobalt.*

The ufual colour of this mineral is peach-bloffom-red, paffing into cochineal and greyifh-red; by expofure to the air it becomes paler, and almoft white. It is found very rarely in mafs, or diffeminated, and ftill feldomer cluftered, or kidney-fhaped; its moft ufual ftate is that of a thin cryftalline covering, or minute drufes of cryftals. The forms which it generally affects are rectangular tables, or tetrahedral acicular prifms, or hexahedral prifms terminated by dihedral fummits: thefe figures, however, are not often determinable, on account of the minutenefs of the cryftals, and their tendency to form radiates and globular groupes. The furface of the cryftals is fmooth and brilliant, and their fracture lamellar. The fracture of the other kinds is radiated, paffing into fibrous. It is tranflucent, and often, when cryftallized, femi-tranfparent.

Before the blow-pipe it gives a faint arfenical odour, and becomes of a dark-grey colour; it is almoft infufible by itfelf, and gives a beautiful blue tinge to borax.

Var. 2. Earthy. *Koboltbefchlag. Cobalt terreux rouge pulverulent.*

The colour of this is the fame as that of the preceding variety. It occurs in a pulverulent or indurated ftate, diffeminated through, or invefting other minerals, and occafionally in mafs. It is dull, opake, and has an uneven earthy fracture. In other refpects it agrees with the preceding.

Sp. IV. *Native fulphat of cobalt. Naturlicher koboltvitriol. Sulfate de cobalt natif.*

At Herrengrund, near Neufohl in Hungary, is found a faline fubftance, in the form of tranflucent ftalactites, of a pale rofe-red colour. It was at firft fuppofed to be fulphat of manganefe, but from an analyfis of Klaproth, it appears to be a pure fulphat of cobalt.

§ 2. *Reduction of the Ores and Analyfis.*

Cobalt is never employed in manufacture in the reguline ftate; the fole ufe of this very valuable metal being to give various fhades of blue colour to glafs and enamel, and when thus employed, it is in the ftate of oxyd. In this ftate it forms either *zaffre*, or *fmalt*, when prepared in the method, which will be defcribed in the next fection.

Many of the cobalt ores are complicated, and difficult to be analyzed completely, nor is it eafy to obtain the cobalt alone from them in confiderable purity. The metals naturally varied with cobalt are the following: 1ft, arfenic, generally in very large quantity, part of which is in the reguline ftate, and, as appears, another part is in the ftate of arfenic acid, which, uniting with the oxyd of cobalt, forms an arfeniat of cobalt, that has often been miftaken for the pure oxyd. The entire feparation of the two is extremely difficult. 2d. Nickel exifts with many cobaltic ores; and being foluble in the fame menftrua, it is not eafily feparated. 3d. Iron, in variable quantity, is found with moft of the ores of cobalt, and is hurtful, as it impairs and degrades the fine blue for which alone cobalt is valued. 4th. Manganefe, which is a ftill worfe admixture. 5th. Copper, in fmall quantity, is fometimes found, which, however, does not much injure the cobalt.

An imperfect analyfis of the common cobalt ores, and which merely has for its object the extraction of the cobalt, is made in the following way: Mix the ore, in fine powder, with charcoal or faw-duft, and roaft it in a low red heat, till the arfenic is driven off, and no arfenical fumes are any longer perceived. Calcine the refidue fome time longer with a ftrong red heat, and in an open fire, and then mix it with about four parts of a faline, reducing flux, (fuch as that compofed of equal parts of tartar and carbonat of potafh) and heat it in a roomy covered crucible, at firft moderately, till the firft fwelling of the materials has fubfided, and then for a quarter of an hour in a heat fully fufficient to melt iron. When cold, a button of reguline cobalt is found beneath a mafs of fcoriæ of an intenfe blue-black colour. From 100 grains of the Tunaberg ore, Klaproth obtained in this way 44 grains of regulus of cobalt, which, however, muft have been ftill very impure, retaining iron and a portion of the arfenic. It may be further purified by alternate deflagration with nitre, and reduction with a faline carbonaceous flux, repeated two or three times, in the way that Lampadius and Tromfdorf have employed with fmalt, as will be prefently mentioned.

The reducing flux for cobalt ore, employed by Beaumé, is the following: Mix 1 oz. of the roafted ore with 3 oz. of black flux, and $\frac{1}{2}$ oz. of carbonat of potafh, cover it when in the crucible with about 1 oz. of falt, and heat the whole, at firft flowly, and afterwards very brifkly for a quarter of an hour.

But, for the purpofes of mere analyfis, where all the conftituent parts of the ore are required to be known with as much precifion as poffible, thefe methods are much too inaccurate to be depended on, and recourfe muft be had to the more tedious and difficult analyfis in the humid way. The procefs given by Taffaert (An. de Chim. tom. 28.) is highly valuable and inftructive.

The method given by Lampadius, of purifying cobalt by fufion is the following: Project in a red hot crucible a mixture of 4 oz. of zaffre, 2 oz. of nitre, and $\frac{1}{2}$ oz. of charcoal. A ftrong arfenical fmell is perceived in the procefs, and a blackifh-grey mafs is left, which is to be again mixed with charcoal and nitre and deflagrated as before: then throw in the crucible 2 oz. of black flux, and heat it intenfely for an hour. This gives a tolerably pure regulus of cobalt, weighing 6 drams. Powder it, and mix it with 1 dram of nitre, and as much manganefe; put it into a luted double crucible, and heat it for an hour in a forge-furnace. The metal, by this operation, lofes all its iron and is nearly pure.

Tromfdorf's procefs is the following: The zaffre, or fmalt, is to be twice detonated with nitre, then wafhed in hot water, which carries off the arfenic now united with the potafh of the nitre, and the refidue is to be digefted in dilute nitric acid, which will only touch the cobalt and leave the iron. The nitrous folution may then be decompofed by an

alkali,

alkali, and the purified oxyd of cobalt, thence resulting, may be afterwards reduced if required.

§ 3. *Preparation of Zaffre and Smalt, or Azure.*

All the zaffre and smalt of commerce are prepared in some parts of Germany, and particularly at Schneeburg in Misnia, which affords a very lucrative trade to Saxony. The following is the method of preparation as given by Kunckel. (See *Neri's Art de la Verrerie.*) The cobalt ore, broken in small pieces, is spread on the hearth of a furnace, like a baker's oven, so constructed that the flame of the wood is reverberated on all sides over the surface; which soon heats it red-hot. A very dense arsenical vapour then arises, which is conveyed from the furnace into a horizontal wooden square trough, or chimney, sometimes of the enormous length of a hundred fathoms, where most of the arsenic is condensed and collected for sale. The cobalt ore is calcined for some hours, till it scarcely emits any more vapours, after which it is taken out, ground to fine powder, replaced in the oven, and calcined a second time, and then again ground and passed through a very fine sieve. This powder is then mixed with about twice its weight of powdered flint or quartz, wetted to the consistence of stiff mortar, and rammed into small barrels, where the mass soon acquires a stony hardness, and is then the *zaffre* of commerce. The reason of using the flints appears to be partly to dilute the cobalt ore, and partly for some purpose of concealment; the exportation of the simple calcined ore being forbidden under heavy penalties.

Smalt, sometimes also called *azure blue*, when finely powdered, (which must not be confounded with the true *azure*, or *lapis lazuli*) is an intensely deep blue glass, made of the calcined cobalt ore and the common vitrifiable fluxes, which is used as a colouring matter for a variety of purposes. The intensity of colour of course depends on the proportion of roasted cobalt ore which it contains, regard being had to its quality, and the proportion of oxyd of cobalt which it is estimated to contain. On an average about equal parts of the roasted ore of potash, and of ground flints are used. This mixture is first *fritted*, and then melted in pots similar to those of glass-houses, and about ten or twelve hours of fusion are required. When the glass is thoroughly fused, it is laded out and dropped into cold water to crack it in every direction, and then ground in a mill made of a very hard stone. At the bottom of the glass-pots a quantity of regulus of bismuth is always found, lying under a mixed alloy of arsenic, iron, and copper.

The grinding of the blue glass is a work of much difficulty, and different degrees of fineness of the powder are obtained by subsequent washing and sifting.

Smalt is a valuable colour, on account of the fine body which it possesses; and being indestructible in any heat, it is useful for all enamel colours, but it will not mix with oil colours, and therefore can only be partially used. Starch is slightly coloured with it to give a small degree of blueness, which corrects the yellow hue which linen and cotton acquires by being worn.

Zaffre is also prepared in Bohemia, Wirtemberg, Silesia, and Lorraine, but the Saxon is preferred.

The oxyd of cobalt contained in the zaffre is still intimately mixed with a small portion of arsenic, partly as arsenic acid, and partly as oxyd of arsenic. If zaffre is digested in liquid caustic ammonia, a red solution is formed, which, on evaporation, deposits a yellow powder, which is a mixture of the oxyds of cobalt and arsenic. If zaffre is boiled in water, a solution is also obtained, which is sensibly acid, and was thought by Brugnatelli to indicate the existence of a cobaltic acid, but Darracq has shewn it to be an arseniat of cobalt.

§ 4. *Chemical Properties of Cobalt.*

Cobalt, when perfectly pure, has a steel-grey colour, not very resplendent, and when slowly cooled, has somewhat of a reticulated texture. It melts at about the fusing point of cast iron.

Cobalt, when heated strongly in contact with air, is converted into a black oxyd, with an increase of about 18 parts on 100; hence 100 parts of the oxyd contain 84.75 of metal, and 15.25 of oxygen. When it retains any arsenic, the colour is reddish.

This metal burns in oxymuriatic acid gas, with a bright white flame.

The sulphuric acid dissolves cobalt with difficulty, but its oxyds more readily. If zaffre, or which is better, the wet precipitate from nitrat of cobalt by carbonat of potash, is digested with sulphuric acid; and the mixture evaporated nearly to dryness, the residue digested with hot water, gives a solution of sulphat of cobalt, which, by slow evaporation, affords the salt in crystals, that are of a fine red when the metal is pure, but greenish when it contains nickel. This salt is soluble in 15 parts of boiling, and 24 parts of cold water.

Nitric acid dissolves cobalt or its oxyd copiously and with great ease by digestion in a moderate heat. The solution is red, or claret-coloured, or yellow, if it holds iron. It scarcely can be brought to crystallize, but by evaporation to dryness and calcination, it leaves a dark red or violet oxyd.

Muriatic acid acts with great difficulty on cobalt, and can scarcely be made to dissolve it, unless by repeated evaporations to dryness and affusion of fresh acid. But it dissolves the oxyds of this metal with much more ease when assisted by heat. The solution is of a rose-red, but when evaporated to dryness and warmed, it acquires a beautiful blue-green, which more approaches to blue in proportion as the solution is free from iron. This singular property of the muriat of cobalt was first discovered by Hellot, and used in making a beautiful *sympathetic ink*, the properties of which have engaged much of the attention of chemists. If the solution be considerably diluted, characters traced by it on paper are scarcely visible when cold, but when held near the fire, they very speedily assume a beautiful blue green, which colour again totally disappears when cold, and may be made to re-appear at pleasure by the same means. The paper, however, should not be heated more or longer than is necessary to produce the full effect. It is found, that not only the pure muriat of cobalt, but any solution of this metal into which muriatic acid, or a muriatic salt, enters, will have the same effect. Hence the commonest method of making this sympathetic ink, and that employed by the inventor, is, to digest zaffre in a moderate heat, with a mixture of about three parts of nitric and one of muriatic acid, diluted with as much water, till a high claret-coloured solution is formed, which should then be diluted with as much water as possible, to prevent the paper from being corroded by the acid. But a much more concentrated solution may be made, which shall not injure the paper, in the following way: Boil some moderately dilute nitric acid or zaffre, till much of the cobalt is dissolved out of it, then add to it any alkali as long as any precipitate takes place; pour off the clear liquor after standing some time, wash the sediment with hot water, and throw it on a filter. Take the sediment which is left on the filter, and put it, while still wet, into a glass flask, and boil it it with diftilled vinegar, which will readily diffolve it, and make a rofe-coloured folution, which may then be made into a fine fympathetic ink, by diffolving in it fome common falt or fal-ammoniac.

It has been mentioned that the colour of the common cobaltic fympathetic ink is green, and when made fimply by diffolving the foluble part of zaffre in nitro-muriatic acid, it is generally a pale grafs green, but in proportion as the cobalt becomes purer, the colour approaches to a bright blue green. This is probably owing to the feparation of iron which the common zaffre contains in abundance, and which may be effected more or lefs perfectly in various methods. The fimpleft (though not the moft economical) is to add to the folution very gradually carbonat of potafh as long as the precipitated oxyd is rofe-coloured, and to ceafe when it begins to have a yellow ochery hue; for the former confifts chiefly of the cobalt, and the latter chiefly of the iron. Then by collecting, wafhing, filtering, and re-diffolving the rofe-coloured precipitate in the nitric or acetous acid, a much purer folution is obtained, which contains very little iron, and gives a blue-green fympathetic ink, when any muriatic falt is added. Another way of feparating moft of the oxyd of iron is to evaporate the nitrous folution nearly to drynefs, and to expofe it for fome time in a fhallow veffel to the air, by which much of the iron will be rendered infoluble, and fubfide as a red ochre, whilft the cobalt will remain in folution. Or elfe the acetited folution of both metals may be alternately evaporated to drynefs, and the foluble part re-diffolved by frefh acetous acid, for two or three times fucceffively, by which the iron will gradually feparate, and the cobalt alone be left.

But to obtain perfectly pure cobalt, feparate from arfenic, bifmuth, iron, and other impurities, is more difficult, for in the above-mentioned proceffes the arfenic acid and oxyd contained in the cobalt ore muft accompany the cobalt and be retained in all the folutions. We fhould therefore recommend the following method: Digeft a quantity of zaffre with nitric acid diluted with about three times its weight of water, and boil them for fome time. After ftanding for a while pour off the clear folution and evaporate it nearly to drynefs. Then dilute it pretty largely with water, which will caufe the bifmuth, if any, to fubfide. Then neutralize any excefs of acid in the filtered folution by any alkali, avoiding to precipitate any of the metal which it contains, and add, cautioufly by drops, fome of a folution of nitrated lead (made by diffolving the cryftals of this falt in water) as long as any precipitate falls down. This latter is arfeniat of lead, and by this means all the arfenic acid of the zaffre will be removed. Then entirely decompofe the clear folution by cauftic potafh, collect and wafh the precipitated oxyd put into a phial, and add to it fome cauftic ammonia, which will diffolve only the oxyd of cobalt. From this ammoniacal folution all the oxyd may be again feparated either by evaporation to drynefs, or by boiling with cauftic potafh, and a very pure black oxyd of cobalt is left, which may be reduced to the metallic ftate by being heated intenfely in a covered crucible lined with charcoal; or it may be diffolved in the feveral acids. This method, however, is expenfive, on account of the quantity of ammonia employed, but it is difficult to exclude the iron totally by any other method.

A triple falt of cobalt, nitric acid, and ammonia, is made by adding ammonia to nitrat of cobalt, which may be cryftallized.

The fixed alkalies have little or no action on cobalt or its oxyds in the moift way, but ammonia diffolves the oxyds largely, as already mentioned.

Tincture of galls give a yellowifh white, and pruffic acid a green precipitate to the folutions of cobalt when free from iron.

Sulphur unites with great difficulty to cobalt by fufion, but the hydrofulphurets and liver of fulphur readily diffolve this metal. Hydrofulphuret of potafh added to the folutions of cobalt gives a very black precipitate, which an excefs of the hydrofulphuret again diffolves. Cobalt ore fufed with liver of fulphur is diffolved thereby, and a brilliant metallic looking mafs is produced, which deliquefces totally by expofure to air, and falls into a dark liquid.

None of the poffible alloys of cobalt deferve any particular notice, for this metal has only a fingle ufe in the arts, namely, that of giving a blue colour to vitrefcent compounds when its oxyd is melted with them, and this colouring power is fo intenfe, that a fingle grain of the pure oxyd (or zaffre in proportion) will give a very deep blue to half an ounce of glafs. When the glafs contains much more than this proportion, the body of colour is fo intenfe as to render it nearly opake, and hence, too, it is of ufe in forming the black gl[illegible] and enamels.

The affinities of cobalt are ftated to be in the following order, *viz.* the gallic, oxalic, muriatic, fulphuric, tartareous, nitric, phofphoric, acetic, arfenic, and carbonic acids, and ammonia. We may add. however, that the difficulty of obtaining pure cobalt, and the variety of metals with which it is ufually alloyed, render this order of affinity fomewhat doubtful.

Cobalt is alfo ufed by fome to exprefs that fuffocative vapour or damp in mines, which often proves fatal to the miners. It is common among the Germans, to fay on this occafion, that the cobalt rofe and choaked them. See Damps.

COBAN, in *Commerce*, a piece of gold coin in Japan, worth 30*s*. fterling.

COBANDI, in *Ancient Geography*, a people of Germany, placed by Ptolemy on the eaftern coaft of the Cimbric Cherfonefus.

COBARRUBIAS, Alonzo De, in *Biography*, an architect of Toledo, who is faid to have been the firft who introduced the Greek and Roman ftyles of architecture in Spain. He was employed by Charles V. to erect the north front, as well as fome other parts of the royal palace of Toledo, in which work, however, he has adopted a mixed ftyle, partaking of the old Gothic as well as of the Greek; probably with the view of rendering the modern part of the building more conformable to the great body of that very ancient fabric. He likewife modernized the vaft and magnificent cathedral of the fame city, and built the extenfive church and monaftery of St. Michael at Valencia. Milizia, Mem. degli. Arch.

COBAYA, in *Zoology*, the Guinea pig. See Cavia *cobaya.*

COBBAN, in *Botany*, a fmall tree like a peach-tree, which grows in Sumatra, called *Perficæ affinis in Taprobana.* C. B. *Arbor Getruph, five coblan*, J. B. It bears a fmall leaf, like that of the tree which produces the *filiqua cathartica*, with fhort branches, and a yellowifh or faffron-coloured bark. The fruit is thick and round like a tennis-ball, inclofing a nut as big as a filbert, which contains a very bitter kernel, tafting like the root of angelica.

The fruit is very proper to quench thirft; but the kernel, however bitter, is far fuperior in virtue. The inhabitants of Sumatra, where the tree grows, extract an oil from the kernel, which is very efficacious in pains of the liver and fpleen, taken inwardly, or ufed by way of unction; and is alfo a fovereign remedy in the pain of the gout, to which the inhabitants of that ifland are very fubject.

From

From the same tree distils a gum, which is very serviceable in the before-mentioned disorders, if it be dissolved with a moderate quantity of oil, and applied to the affected parts by way of cataplasm.

COBBE', in *Geography*, the capital town of Dar-fûr, in Africa, situated almost on the direct road from the north to the south extremity of the country. N. lat. 14° 11'. E. long. 28° 8'. The town is more than 2 miles in length, but very narrow; and the houses, few in number, each of which occupies within its inclosure a large portion of ground, are separated by considerable waste. It is full of trees of several kinds, which give it an agreeable appearance at a small distance; for, being situated on a plain, it is not distinctly visible more than 4 or 5 miles in any direction. During the rainy season, the ground on which it stands is surrounded by a torrent. Fronting it to the east, the town itself extending from north to south, is a mountain or rock, distinguished by the same appellation, which is the resort of hyænas and jackals. The inhabitants are supplied with water from wells of small depth, some of which are dug within the inclosure of many of the houses; but the best of them are in or near the bed of the torrent. The town is surrounded by villages at small distances, in various directions, which are dependent upon it, and increase its apparent population. The inhabitants of Cobbé are, for the most part, merchants, employed in trading to Egypt, the greater number of whom come from the river, and some of them are natives of that country. Some Egyptians, chiefly from Saïd, a few Tunisines, natives of Tripoli, and others, come and go with the caravans, remaining only a sufficient time for the sale of their goods. Others have married in Dar-fûr, and are now perfectly naturalized, and recognized as subject to the sultan. The fathers being dead, the children succeed to their occupations. The other inhabitants are foreigners, from Dongola, Mahas, Sennaar, and Kordofân, who are generally indefatigable in commerce, but daring, restless, and seditious, so that the present sultan has made some efforts to banish them from his dominions; they are the offspring of those whose parents have emigrated, and who have themselves been born in Dar-fûr; the latter are often people of debauched manners, and not remarkable for the same spirit of enterprise as the actual emigrates. The people first mentioned commonly use among themselves the language of Barabra, though they also speak Arabic. The latter are generally unacquainted with any language but the Arabic. They usually intermarry with each other, or with the Arabs. Some, avoiding marriage with Furian women, merely cohabit with their slaves. Persons of both these descriptions are easily distinguishable from the natives of the country, being usually of a more olive complexion, and having a form of visage more nearly resembling the European, with short curly black hair, but not wool. They are a well-sized and well-formed people, and have often an agreeable and expressive countenance, though sometimes indicating violent passions, and a mutable temper. South-east of the town, in a large open space, a market is held on Monday and Friday, in every week, in which provisions of every kind are sold, including all the commodities which the country produces, and also those that are brought from Egypt, and other places; and from this market all the villages, six or eight miles round, derive their supplies. About the month of December grain is cheapest, and at this time the inhabitants commonly lay in their annual stock. Two, or sometimes three, pecks of millet may be had for a string of beads, worth about one penny sterling, at Cairo. Slaves, though sometimes brought to the market, are commonly sold privately, which is frequently complained of as an evil, because it facilitates the sale of such as have been stolen from other quarters. In the town they have four or five "mectebs," in which boys are taught to read, and, if they wish it, to write. The lecturer instructs gratuitously the children of the indigent; but those who are in easy circumstances make a small remuneration. Two or three lectures in the Koran, and two others in what they call "elm" theology. In this town is one small mosque, being a square room, formed by walls of clay, where the fukkara, or pretenders to extraordinary sanctity, blending with it brutal intolerance to strangers, meet thrice in the week. A large mosque, the area of which was about 64 feet square, and the walls about 3 feet thick, was begun when Mr. Brown visited this place; but though the material was merely clay, the work advanced very slowly. Browne's Travels in Africa, ch. 17.

COBBESECONTE, or COPSECOOK, signifying, in the Indian language, the land where sturgeons are taken, is a small river which rises from ponds in the town of Winthrop, in the district of Mainé, and falls into the Kennebeck within 3 miles of Nahunkeag island, and 15 from Moose island.

COBBING, in *Sea Language*, a punishment inflicted at sea on those who quit their station during the night watch. It consists of a number of strokes on the breech with a flat piece of wood, called the *cobbing-board*.

COBBS, in *Geography*, a town of America, in the state of Virginia; 20 miles S.W. of Richmond.

COBCAR-ING *Iron-works*, are situate on a branch of the Dearne and Dove canal, in Yorkshire. See CANAL.

COBELLA, in *Zoology*. See COLUBER *venosus*, called by Laurenti *aspis cobella*.

COBEQUIL, or COLCHESTER *River*, in *Geography*, a river of Nova Scotia, which rises within 20 miles of Tatamogouche, on the N.E. coast of Nova Scotia; from thence it runs southerly, then S.W. and W. into the east end of the basin of Minas. At its mouth is a bank, with a good channel on each side, so that vessels of 60 tuns burden may pass, and sail 40 miles up the river. On its banks are some scattered settlements.

COBER, a river of England, in the county of Cornwall, which runs into the English channel a little below Helston.

COBESEY, in the district of Maine, in N. America. See PITTSTON.

COBEZA, or COBIJA, an obscure port and village in the audience of Los Charcas, in Peru, South America; the place is inhabited by about 50 Indian families, and is the most barren spot on the coast. It is, however, the nearest port to Lipes, where are silver mines, and also to Potosi, which is above 100 leagues distant through a desert country.

COBHAM, a small town of America, in the state of Virginia, on the south bank of James river, opposite to Jamestown; 20 miles N.W. of Suffolk, and eight or nine S.W. of Williamsburg. N. lat. 37° 7'. W. long. 76° 55'.

COBHAM *Isle*, an island mentioned by captain Middleton in the journal of his voyage for finding a north-east passage. Its two extremes bear N. by E. and E. by N. in N. lat. 63°, and E. long. from Churchill, 3° 50', which he takes to be the "Brook Cobham" of Fox.

COBI, as it is called by the Tartars, and denominated *Chamo* by the Chinese, an immense desart of Tartary, running in a parallel direction from the east to the west, south of the Altaian ridge, and occupying almost the whole southern part of the country of the Kalkas. This desart is reckoned to be more than 100 leagues in length from east to west, and almost the same in breadth from north to south, and even more towards the western parts; and it presents nothing to view but immense plains of sand, fometimes moveable, fometimes folid. Thefe plains are here and there interrupted by fome little hills, on which are feen a few bufhes, but not a fingle tree. It is in general dry, and deftitute of pafturage and water of every kind, except a fmall number of pools in which the rain is collected, and a few bad wells that occafionally occur. Its fituation is very high, and it may be eafily perceived on leaving China, that one muft afcend confiderably to crofs it; the cold, on that account, is exceedingly fharp, and continues very long. The great quantity of falt with which the fand is impregnated greatly contributes to this temperature. On digging only a few feet below the furface, the earth may be found frozen in every feafon of the year. The fands of this region are very inconvenient to travellers, and dangerous to horfes, many of which daily perifh; and, therefore, the neighbouring Tartars, when they traverfe them, generally make ufe of camels, becaufe thefe animals require little food, and can live without water for feveral days.

COBIJA. See COBEZA.

COBILUS, in *Ancient Geography*, a river of Afia Minor in Bithynia, according to Valerius Flaccus, fuppofed to be the Cobulatus of Livy.

COBIOMACHUS, a name given by Cicero to a village of Gallia Narbonnenfis, fuppofed to be the fame with the modern *Cabaignac*, between Touloufe and Narbonne.

COBITIS, in *Ichthyology*, a genus of abdominal fifhes, diftinguifhed by the following character.

The head is fmall, oblong, and deftitute of fcales; eyes fituated in the upper part of the head; nape flat. Gill-membrane with from four to fix rays; gill-cover confifting of a fingle piece, and clofing beneath. Body covered with mucus, and fmall, thin, deciduous fcales; and nearly of equal thicknefs from the head to the tail; back ftraight, with a fingle fin; lateral line fcarcely confpicuous; vent neareft the tail.

Species.

BARBATULA. Cirri fix, head unarmed, and compreffed. Linn. *Enchelyopus*, &c. of Klein, and *Cobitis fluviatilis* of Ray.

The *Cobitis barbatula* is the bearded loche of Englifh writers. This fifh is an inhabitant of clear rivulets in many parts of Europe. The body is finely varied with pale brown, white, and black; it is a fertile fifh, and of exquifite flavour, and is on that account cultivated with much affiduity as an article of luxury for the table in fome parts of Europe. Donov. Brit. Fifhes.

TAENIA. A forked fpine under each eye. Linn. *Cobitis aculeata*, Marfd. Dan. *Taenia cornuta*, Willughby.

This alfo is a native of Europe; it inhabits frefh waters, and is obferved to lurk under ftones, whence in England it has obtained the name of groundling; it feeds on worms, aquatic infects, and fmall fifhes; when handled makes a hiffing noife. The colour is yellowifh, with four rows of brown fpots, and like the former fpecies this has fix beards or cirri to the mouth.

FOSSILIS. Cirri eight; a forked fpine over each eye. Linn. Fn. Suec. *Muftela foffilis*, Marfd. *Beyfzker*, Gefner.

This fpecies is the largeft of the genus; it inhabits boggy places, and muddy lakes, and ftreams in feveral parts of Europe, but is moft frequent in Germany. The great loche is ufually from ten to twelve, or at the utmoft fifteen inches in length, of a dull yellowifh-brown colour, marked above by feveral longitudinal ftripes of dark brown or black, and which extend the whole way from the head to the tail. This fpecies conceals itfelf during the winter, or when the marfhes it inhabits begin to grow dry, at fome diftance beneath the furface of the mud. According to Bloch this fifh is obferved to be unufually reftlefs; quitting the muddy bottom in which it generally refides, and fwimming near the furface of the water. It is a prolific fifh, very tenacious of life, and excellent food.

HETEROCLITA. Head without cirri; dorfal and anal fins fpotted with white, and the tail barred with black.

Defcribed by Dr. Garden as a native of Carolina, where, according to that writer, it is known by the name of mudfifh. The length is about four inches: the body roundifh, and covered with large fmooth fcales, and the colour beneath yellowifh. The head is flattifh, lips denticulated; dorfal and anal fin placed oppofite, and fituated at a great diftance from the head; they are blackifh and powdered with pale tranfparent fpecks. Gmelin expreffes fome doubt whether this fifh in reality appertains to the genus *cobitis*.

JAPONICA. Head without cirri, depreffed; jaws armed with teeth. Japanefe loche.

A native of Japan, and firft defcribed by Houttuyn, in the 20th volume of the Haarlem Tranfactions. The length is five inches, and the body is of a roundifh form. The dorfal fin contains twelve rays; the pectoral eleven, ventral eight, anal nine, and tail twenty.

ANABLEPS. Cirri two; head depreffed, eyes prominent. Linn. *Anableps* Arted. *Anableps, tetropthalmus*, Bloch.

Linnæus confiders this as a fpecies of cobitis, but we are clearly of opinion that notwithftanding its general refemblance to fifhes of this genus, the very extraordinary, and indeed, peculiar conftruction of its eyes at once removes it from that genus of fifhes. Thefe eyes are protuberant, and have double pupils, fo diftinctly marked, that at the firft view the fifh appears in reality to be furnifhed with a pair of eyes on each fide of the head. Bloch conftitutes a new genus of this fingular fifh under the generical appellation of *anableps*, a genus we fhould adopt could the article be readily referred to its alphabetical order in the Cyclopædia. Linnæus, however, having defcribed it as appertaining to the genus cobitis, there can be little impropriety in allowing it to remain as a fequel to that genus. This fifh was firft defcribed by Artedi, who examined fome fpecimens of it in the mufeum of A. Seba, which were received from South America, the region it inhabits. It is faid principally to live in the rivers of Surinam, near the fea-coafts.

The length of this fifh is from fix to eight inches, or fometimes rather more. It is of a very compreffed form, and is covered with moderately large rounded fcales, which are fmaller in proportion on the head than any other parts. The colour is a pale yellowifh brown, marked, like the great loche, with four or five longitudinal blackifh ftripes. In the ftructure of its eyes it differs from every other fifh known; thefe eyes are extremely protuberant, fituated on the upper part of the head, and feem each divided into two diftinct eyes, united in a fingle tubular receptacle; it appears, however, on diffection, that though the anterior half of each eye feems to be double, or furnifhed with two pupils, yet the cryftalline is fingle; the appearance of a double eye on each fide arifing merely from the deep divifion of the anterior region. It is afferted alfo by Gronovius, that the anal fin varies in its ftructure in different individuals, being in fome of a fimple or regular form, and furnifhed with nine foft rays, while in others it is formed into a tube, which is fometimes accompanied by a fmall additional fin.

COBITIS *aculeata*, called alfo *cobytis oxyrynchus*, and *dacolithus*, names given by Aldrovandus, Jonfton, Gefner, and other old writers, to the *Cobitis taenia* of modern naturalifts. See COBITIS *taenia*.

COBIUS.

COBIUS. See GOBIUS.

COBLENT, HERMAN, in *Biography*. See H. COLAERT.

COBLENTZ, in *Geography*, a city of Germany, in the circle of the lower Rhine, in the electorate of Treves, or according to the French arrangement, the principal place of a district, and capital of the department of the Rhine and Moselle, including three communes, and containing, according to the statement of Tinseau in 1803, 10,000 inhabitants; and according to Render in his "Tour through Germany," (vol. i.) about 16,000, all of whom are Roman Catholics. They are generally tall, with agreeable features, and expressive countenances.

The population of the whole district in 1803 is stated by Tinseau to have been 69,900. It comprehends 209 communes, distributed into 12 cantons, *viz.* Coblentz, Andernach, Boppard, Cochheim, Raiserfech, Luzerath, Mayen, Munstermaifield, Polch, Ruberach, Tries, and Zell. In this district there are considerable bleaching yards, and some manufactures of woollen and linen cloth, and also of leather. The soil is moderately fertile, affording excellent vineyards; and the hills are covered with trees. The canton of Mayen has three quarries of slate and lime, together with some lead and iron mines. The mineral springs of Andernach are denominated Tinitein, or Tunistein water. The canton of Luzerath has a warm bath.

Almost immediately above the city, the river Moselle unites with the Rhine, and forms a kind of triangle, from which circumstance it derives its name, in Latin *Confluentia*. Over the Moselle is a stone bridge, constructed in the 14th century, which has 14 arches, 520 feet in length, and of such a height that vessels may pass under it without lowering their sails. The flying bridge, or bridge of boats, by which passengers may cross the Rhine three times every hour, to the small town of Thal, presents a very uncommon and pleasing sight. In the time of the Romans, Coblentz was the station of the first legion; and afterwards it became the residence of the successors of Charlemagne. In 1249, it was encompassed with walls, and since that time it has been fortified. The streets of Coblentz are generally regular, the pavement tolerably good, and the city well lighted in winter.

On the eastern bank of the Rhine, the elector finding the situation of the old palace, in the vale of Ehrenbreitstein, insalubrious and inconvenient, has lately built another very elegant and sumptuous one, where he has since resided. This city contains three large churches, two of which are collegiate, several convents, and other noble buildings. It has also a Gymnasium or academical school, in which a new plan of education is adopted, with respect both to the classics and sciences, which, from the encouragement it has received, is likely to produce the best effect on the customs and manners of the inhabitants, and to promote in a very great degree the improvement of the city. Commerce, however, notwithstanding the advantageous situation of the city near the Rhine and the Moselle, does not make any great progress; one cause of which is the vicinity of Mentz and Cologne, which, by duties and tolls, impede the natural course of trade. Another cause is religious intolerance, which long prevailed here, but is now in a great degree removed by the enlightened policy of the elector. Coblentz was formerly imperial, but was taken by the French in October, 1794, and ceded to them by the treaty of Campo Formio, in 1797. The country around this city is in every respect very romantic. The hills on the right and left form an amphitheatre, and some of them are covered with bushes. The meanders of the rivers Lahn and Moselle, which join the Rhine, exhibit a pleasing prospect. Nearly opposite to this city is the ancient fortress of Ehrenbreitstein, which is seated on the summit of a stupendous rock about 800 feet above the level of the river, and when supported by a competent garrison, is deemed impregnable; it communicates with Coblentz by subterraneous passages cut in the solid rock, and is plentifully supplied with water from a well 286 feet deep. In the arsenal, belonging to this fortress, is a curious cannon, called "Der Vogel Greif," *i. e.* the bird called Griffin, 20 feet long, about two feet diameter in the bore, and four in the breech. This cannon, it is said, when discharged with a ball of 160 pounds weight, will carry it to Andernach, about 12 miles from thence. The ancient residence of the electors of Treves is situated at the foot of the castle. The view from the pinnacle of the fortress commands the country round Coblentz for about 100 miles. A considerable leather manufactory has been established at this place, under the patronage of the elector; and another at the distance of about two miles at Vallender. They receive their hides directly from Buenos Ayres in South America. The prison belonging to this fortress, and the treatment of those criminals who are confined in it, have been long a reproach to German jurisprudence. Coblentz is situated at the distance of 36 miles N.W. from Mentz, 54 N.E. from Treves, and 82 E.S.E. from Liege. N. lat. 50° 24′. E. long. 7° 40′.

COBLENZ, a town of Swisserland, in the district of Baden, at the confluence of the Aar and the Rhine, 10 miles N.N.W. of Baden.

COBLESKILL, a new town of America, in the state of New York, and county of Schoharie, incorporated in 1797.

COBOB, a name of a dish among the Moors. It is made of several pieces of mutton wrapt up in the cawl, and afterwards roasted in it; the poorer people, instead of the meat, use the heart, liver, and other parts of the entrails, and make a good dish, though not equal to the former. Phil. Transf. N°. 251.

COBOOSE, in *Sea Language*, is derived from the Dutch *kambuis*, and denotes a sort of box, resembling a centry-box, used to cover the chimneys of some merchant-ships. It generally stands against the barricade, on the fore-part of the quarter-deck. It is called in the West Indies *cobre vega*.

COBOZE, in *Geography*, a small island in the Indian sea, near the east coast of Siam. N. lat. 12° 43′. E. long. 97° 20′.

COBRA, in *Zoology*, a species of Coluber in the Gmelinian system. See COLUBER.

COBRA *Americana* of Seba, is COLUBER *subalbidus* of modern authors.

COBRA *Lachesis* of Laurenti, is COLUBER *lachesis* of Gmelin.

Besides these it is to be observed there are several distinct kinds of snakes, known under the general and indefinite title of cobra, some of which it would be difficult to reduce with any degree of certainty to the modern nomenclature. *Cobra de las cabeças* is of this description; it is an American species of serpent, whose bite is said to be very fatal: this kind lives under ground and feeds on ants. *Cobra de coral* is also a native of America, and is called by the natives *Ibiboca*. This is about two feet in length, and is much variegated with red. *Cobra de cipo* is likewise an American snake called by the natives of Brasil, *Boitjapo*.

COBRAS *de Capelio*, the Portuguese name of a kind of serpent, called by some authors, *serpens incoronatus, diademate, seu conspicillo insignis*, and also the spectacle snake, from the strange double ocellated spots on the back of the head

head and neck, which bear some resemblance to a pair of spectacles. It inhabits India, and is said to be the most poisonous of its tribe. See COLUBER NAJA.

In the second volume of the "Asiatic Researches," we have an account by John Williams, esq. of six cases of persons, in the most dangerous situations, in consequence of being bitten by the cobra de capello, who were cured by the internal and external use of volatile caustic alkali. The dose was a tea-spoonful, repeated according to the necessity of the case. The author above observes, that convulsions of the throat and fauces are a constant symptom of the bite of this serpent; but he never knew an instance of the volatile caustic alkali failing in its effect, where the patient has been able to swallow it.

COBRAS, in *Geography*, an island of South America, in the Atlantic, near the coast of Brasil, on the south side of the river Janeiro, opposite the city.

COBRE, EL, a town of the island of Cuba, ten miles W. of St. Jago.

COBRE *de verd*, Cobre verde, in *Zoology*, the name given by the Portuguese in America, to a species of serpent, called by the natives Boiobi. This is the BOA CANINA of Linnæus.

COBULATUS. See COBILUS.

COBUM, in *Ancient Geography*, a river of Asia in the territory of Colchis; the source of which, according to Pliny, was in mount Caucasus, and it had its course among the people called Suani. Arrian mentions it under the name of Chobus. It discharged itself into the Euxine sea.

COBURG, PRINCIPALITY of, in *Geography*, a district situated near the river Saal, between the territories of Bareith, Thuringia, Henneberg, and Bamberg, in the circle of Franconia, but dependent on the circle of Upper Saxony. It formerly belonged to the counts of Henneberg, but passed by marriage to the house of Saxony, and is divided among four branches, Saxe-Coburg-Saalfeld, or Saxe-Saalfeld, Saxe-Meinungen, Saxe-Gotha, and Saxe-Hildburghausen. The land is generally fertile, and the inhabitants export corn, wool, fat cattle, tiles, works in wood, pitch, and pot-ash.

COBURG, a town of Germany in the circle of Upper Saxony, but insulated in Franconia, of which it formerly made a part, when the counts of Henneberg possessed it in the 14th century. It is now the residence of the dukes of Saxe-Saalfeld, and is seated on the river Irtsch, in a valley between two mountains. The town and suburbs are surrounded by a wall. Here are four churches, and a college founded by John Casimir, duke of Saxony, in 1597, on which the emperor Leopold, in 1677, conferred such extraordinary privileges, that it might be said to rival some universities, and a public school, and also manufactures of gold, silver, china, and petrified wood, with which the country abounds. As Luther resided some months at Coburg in the year 1530, the archives may be regarded as a treasury of authentic papers, relating to the reformation. Coburg is 23 miles N. of Bamberg, and 40 S. of Weimar. N. lat. 50° 14'. E. long. 11° 1'.

COBUS, in *Ancient Geography*, a river of the Bosphorus, which flows, according to Pliny, from the Caucasus.

COBWEB. See WEB and SILK.

COBWEB, in *Ornithology*, a name given in Merton's History of Northamptonshire to the spotted fly-catcher, or *muscicapa grisola* of Linnæus and Gmelin.

COCA, in *Commerce*, a measure in Japan, equal to an English pint.

COCA, in *Geography*, a town of Spain, in Old Castile, on the Eresma; 24 miles S.S.E. of Valladolid, and 22 N.W. of Segovia.

COCABA, in *Ancient Geography*, a place of Asia, in the territory of Bashan, in the vicinity of Palestine, where the heresiarch Ebion is said to have lived.

COCALA, a place in Asia, on the Indian sea, in the country of the Oritæ. Arrian. This town of India, is supposed to be the *Cicacole* of modern times. See CICACOLE.

COCALIA, a town of Asia, placed by Ptolemy in the interior of Pontus Cappadocius.

COCALICO, in *Geography*, a township of America, in the state of Pennsylvania, and the county of Lancaster.

COCAMA, a lake of South America, which, at 5° 14' S. lat., by a narrow channel, enters the eastern side of the river Gualaga. This lake is about 1½ league in circumference; and on the bank is a dry, elevated soil, on the top of which stands a missionary settlement, where reside the president of the missions, and the lieutenant-governor. The number of Christians is 8895, with 19 curates, and a superior of the missions; each of the former having 200 dollars a-year, and the vicar 333, paid at the treasury of Quito, and chiefly remitted in effects; while the Indian servants hunt and fish, and cultivate small fields of rice and sugar-canes. Boys of 10 or 12 years of age, are trained by an useful policy to the magistracy, being annual inspectors of the conduct of their comrades, and correcting small offences, whilst rare examples of crimes are reported to the judges. Thus offences are avoided, and young persons are trained to sincere and good conduct. See MAYNES.

COCANICUS LACUS, in *Ancient Geography*, a lake situated on the southern coast of Sicily, which, according to Pliny, produced salt.

COCCAPANI, SIGISMONDO, in *Biography*, a painter and architect, born at Florence, 1583. Early in life he shewed a strong inclination towards the mathematics, and he afterwards studied painting and architecture under Lodovico Cigoli. His first work of painting was an altar-piece in the church of St. Ponziano at Lucca. In the year 1610, he assisted his master in the paintings which he was then executing in the Paoline chapel in the Vatican. Few of his pictures are in public, but many of considerable merit, and particularly some excellent portraits, are to be found in the private collections of Florence. Many years of his life were spent in composing a treatise on architecture, mechanics, hydraulics, &c. illustrated by geometrical figures; which, for its ingenuity and clearness, was honoured with the approbation of the celebrated Galileo. About the year 1630, he was employed, in competition with other artists, to make designs for the façade of St. Maria del Fiore at Florence; which fine church, however, still remains without one. This artist died, much respected, in the year 1642. Baldinucci. Orlandi.

COCCAPANI, GIOVANNI, elder brother of the above-mentioned artist, was born in Florence in 1582. He was first intended for the law, and took his doctor's degree, but he afterwards applied himself more especially to the study of the mathematics, mechanics, and civil as well as military architecture; in each of these branches of science, he soon became so eminent, that his instructions were eagerly sought by many of the young nobility of Florence, as well as foreigners, with whom he ever after kept up a literary correspondence. In 1622, he was called to Vienna, and employed by the emperor in the quality of military engineer; and he afterwards received a grant of lands for his services. Upon his return to Florence, he built the fine palace called Villa Imperiale, for the grand duke; and erected the convent of the nuns of the order of Santa Teresa, with the church in the form of an hexagon, and a well-proportioned cupola.

cupola. The grand duke of Tuſcany having ſounded a college for the ſtudy of the mathematics, Coccapani was choſen profeſſor, nor would he abandon his native city when, upon a future occaſion, he was invited to occupy a ſituation of the ſame kind in Rome, ſtill more honourable. Several extraordinary pieces of machinery were found at his death in 1649, and one in particular, which, by the help of 30 flaſks of water, placed in a box ingeniouſly formed to receive it, was enabled to grind corn, and at the ſame time print copper-plates, and perform various other functions. Baldinucci. Milizia. Mem. degli Arch.

COCCEIRA, in *Botany*, a name by which ſome authors have called the cocoa-nut tree, the *palma nucifera Indiæ* of moſt writers.

COCCEIUS, JOHN, in *Biography*, an eminent theologian, was born at Bremen in 1603, and in 1630 he was made Hebrew profeſſor in the univerſity there. In 1650 he was choſen profeſſor of theology at Leyden, and rendered himſelf diſtinguiſhed by the peculiarity of his opinions. In explaining the Scriptures, he always looked beyond the literal meaning to ſomething that ſhould wear the appearance of myſtery. He regarded the Old Teſtament as a perpetual repreſentation, or mirror of the hiſtory of Chriſt, and his church; he maintained, that all the Jewiſh prophecies have a relation to Chriſt, and that his miracles, actions, and ſufferings, and thoſe of his apoſtles, were types of future events. He was peculiarly attached to the book of Revelations, and believed in common with many divines in almoſt every age of the Chriſtian church, that there would be a viſible reign of Chriſt upon earth, which ſhould deſtroy the kingdom of Anti-chriſt. Cocceius was oppoſed in ſeveral of his darling tenets by Voet; hence in church hiſtory we have the party names of Cocceians and Voetians. Cocceius died at Leyden in 1669, and his works were collected after his death in 10 vols. fol., eight of which were publiſhed at Frankfort in 1689, and the remaining two at Amſterdam not till 1706. He was a man of great erudition, indefatigable induſtry, and the moſt ardent piety; his many virtues did not, however, ſcreen him from the attacks of his contemporaries, by ſome of whom he was branded as a heretic: a fate to which the beſt men in every age have been ſubject. Nouv. Dict. Hiſt.

COCCEIUS, HENRY, a celebrated civilian, was born at Bremen, 1644, and educated at Leyden. After having travelled in various parts of Europe, he became profeſſor of law at Heidelberg, where he was created privy counſellor of ſtate. On the capture of this city in 1688, he loſt his library, and immediately went to Utrecht. Here he ſtayed but two years, when, in conſequence of an invitation from the elector of Brandenburg, he undertook the profeſſorſhip of law at Frankfort on the Oder. By this prince he was conſulted on the moſt important ſtate affairs, and his reputation gained him the rank of baron of the empire, in the year 1718, an honour which he ſcarcely enjoyed a ſingle year. He died in 1719, leaving behind him the character of a great man, celebrated as well for his integrity and diſintereſtedneſs, as for his aſſiduity in every thing that he undertook. His principal works are "Juris Publici Prudentia compendioſe exhibita," 1695, 8vo. "Prodromus Juſtitiæ Gentium," 1719, 4to. "Deductiones, Conſilia, Reſponſa in Cauſis illuſtrium," 1725, fol. and "A collection of Theſes," in 4 vols. 4to. He left a ſon, Samuel, who was diſtinguiſhed as a ſtateſman in the court of Pruſſia, under Frederic the Great, and who drew up the Frederician code, and publiſhed an edition of Grotius "On War and Peace," in 5 vols. 4to. He died in 1755. Nouv. Dict. Hiſt. Du Freſnoy.

COCCHI, ANTHONY, a learned Italian phyſician, was born at Florence in 1695, where he received the rudiments of his education. At a proper age, he was ſent by his father to France, to various parts of Germany, to Holland, and at length to England, every where aſſociating with, and cultivating the intimacy of the moſt diſtinguiſhed philoſophers and phyſicians, among others, with Boerhaave, ſir Iſaac Newton, and Dr. Mead. It was on the ſuggeſtion of Dr. Mead, that on his return to Italy, while filling the chair of profeſſor of anatomy and ſurgery at Florence, he was induced to publiſh "Græcorum Chirurgici Libri; Sorani unus de Fracturarum ſignis, Oribaſii duo de Fractis, et Luxatis, ex Collectione Nicetæ, Florent." 1754, fol. The manuſcripts from which this curious work is publiſhed, are in the library of the Medici at Florence. "Oratio de Uſu Artis Anatomicæ, Florent." 1736, 4to. The author gives a ſhort hiſtory of anatomy and ſurgery, in which he denies that the ancient anatomiſts, Herophilus and Eraſiſtratus, were accuſtomed to diſſect the bodies of men, while living. "Medicinæ laudatio in Gymnaſio Piſis habita," 1727, 4to. Spoken on opening a courſe of lectures at Piſa, where he had been appointed profeſſor, prior to his returning to Florence. "Del vitto Pythagorico," Flor. 1743, and 1750, 8vo. It has been ſeveral times re-printed. The author thinks a vegetable diet beſt ſuited to the conſtitution of man. He wrote alſo on cold bathing, which he commends. "On the Baths at Piſa, and Sopra Aſclepiadea." This was publiſhed by his ſon, Raymond Cocchi, who ſucceeded his father as profeſſor of anatomy, and phyſician to the public hoſpital at Florence. Haller Bib. Chirurg. Eloy. Dict. Hiſt.

COCCHI, ANTHONY CELESTINE, cotemporary, and probably related to the above, practiſed medicine, with credit, at Rome, in the early part of the laſt century. He was teacher of botany there, and author of the following: "Epiſtola ad Morgagnum, de lente cryſtallina oculi, vera ſuffuſionis ſede," Rome, 1721, 4to. "Epiſtolæ Phyſico-Medicæ ad Lanciſium et Morgagnum," Rome, 1725, 4to. Some judicious obſervations are offered by the author on the gaol or hoſpital fever, on aneuriſms, and on a caſe which occurred to the author of a dilatation of the vena cava; alſo on a caſe of hyſteria; a tranſlation into Latin of "Zenophon's Ambrocoſmus et Anthia," 1726, 4to. London. "An Oration on opening the botanical garden at Rome, to which the author was appointed curator; and a relation of a caſe of ſmall-pox, preceded by a paroxyſm of convulſion, which was appeaſed, we are told, by bleeding the patient, and immerſing the extremities in warm water." "Diſſertatio Phyſico-practica continens vindicias Corticis Peruviani," Rome, 1748, 8vo. The prejudices which at that time prevailed againſt the uſe of the Peruvian bark, which are here judiciouſly combated, have long ſince ſubſided. Haller. Bib. Med. Eloy. Dict. Hiſt.

COCCHI, GIOACCHINO, a Neapolitan opera-compoſer, of conſiderable reputation in Italy, and mentioned by Rouſſeau in his Lett. ſur la Muſ. Fran. in 1750, among the eminent maſters then flouriſhing in that country. It was in the beginning of the Mattei's opera regency, 1757, that Cocchi came to London, where he compoſed a great number of operas, ſerious and comic, arranged paſticcios, and publiſhed miſcellaneous ſongs, ſymphonies, or opera overtures, in parts, and pieces adapted to the harpſichord. Coming from Naples, where good compoſers abounded, he had good taſte, and knowledge in all the mechanical parts of his profeſſion; but his invention was very limited, and even what he adopted from others, became languid in paſſing through his hands. The only drama ſet by this compoſer, during his 15 years reſidence in this country, was "Ciro Riconoſciuto," in 1759. The air "Rende mi il figlio mio," was happily ſet, and was ſtill more happily ſung

by

by Mattei. This air is full of ſpirit and paſſion, and perfectly ſuited to the ſituation of the character by which it was performed. This is one of the firſt capital opera airs without a ſecond part and *da capo*. The duet has conſiderable merit, but too many of the paſſages are *alla ſcozzeſe*. This drama was repreſented during a great part of the remainder of the ſeaſon. It was in this opera that Tenducci was firſt noticed on our ſtage; and, though a young performer, and only ſecond in rank, he had a much better voice and manner of ſinging than Potenza, to whom he gave precedence.

In 1760, Cocchi ſet "La Clemenza di Tito," but diſcovered no new reſources in its compoſition. At the end of May of this year, "Erginda," written by Apoſtolo Zeno, now ſet by Cocchi, was alſo brought out, but after three repreſentations, to very thin houſes, the ſeaſon was cloſed, June 7th, without its having afforded much rapture to the public, or profit to the *impreſaria;* who not having been able to procure a capital ſinger to perform the firſt man's part, and Cocchi's invention, which was never fertile, being now exhauſted, the ſeaſon paſſed on rather heavily; as did his "Tito Manlio" in 1760, which only ſuſtained three repreſentations. The ſeaſon cloſed this year with an occaſional "Grand Serenata," and the next began with an occaſional drama, "Le Speranze della Terra," both compoſed by Cocchi, both ſhort-lived, and little noticed. In 1762, he compoſed two comic operas, to which even the animated performance of the admirable Paganini could not give long life. Cocchi was quite exhauſted long before his comic operas were produced. His invention did not flow in torrents, it was but a rill at its greateſt ſwell; and now, with hardly a ſingle ſmile upon any one of the airs, his heavy and thread-bare paſſages were doubly weariſome. Indeed, his reſources in the ſerious ſtyle were ſo few, that he hardly produced a new paſſage after the firſt year of his arrival in England; but in attempting to clothe comic ideas in melody, or to paint ridiculous ſituations by the effects of an orcheſtra, he was quite contemptible. Without humour, gaiety, or creative powers of any kind, his comic opera was the moſt melancholy performance I ever heard, ſays Dr. Burney, in an Italian theatre.

When Cocchi firſt arrived in England, he brought over the new paſſages that were in favour at Rome and Naples, to which, however, he added ſo little from his own ſtock of ideas, that, by frequent repetition, the public was ſoon tired of them; and his publications in this country are now as much forgotten as if he had lived in the fifteenth century. Indeed, all the animation and exiſtence they had, were conferred on them by the performance of Elſi and Mattei. He remained here long enough to ſave a conſiderable ſum of money by teaching to ſing. Plutarch informs us, that Dionyſius the tyrant of Syracuſe, when he had loſt his kingdom, became a ſchoolmaſter, the common reſource of opera compoſers and ſingers, who, after being *dethroned* in the theatre, often ſubmit to the ſame drudgery.

The operas which he compoſed in England have been ſpecified till the year 1762, when his engagement as opera-compoſer ceaſed. In 1765, he compiled a ſerious paſticcio, called "La Clemenza di Tito," in which he introduced a few of the ſongs from his own former opera of that name, which had been performed in 1760; and in 1771, he compoſed an opera called "Semiramide Riconoſciuta," and this was his *finale;* but the nation had been too long accuſtomed to better muſic to liſten to it with much pleaſure.

About 1772, he retired to Venice, where he had been maeſtro of a conſervatorio before his arrival in England; and there he enjoyed in eaſe and tranquillity the fruits of his labours, ſeveral years. The patrons of the conſervatorios of Naples and Venice, with great liberality and kindneſs to other nations, grant permiſſion to the eminent compoſers whom they elect maſters of the conſervatorios, to accept of engagements in foreign countries, without diſpoſing of their places, but to deputies properly qualified for ſuperintending theſe muſical eſtabliſhments, which are reſtored to the travelling maſters on their return. This indulgence was granted to Haſſe, Galuppi, Sacchini, Bertoni, &c. during the many journeys which they took profeſſionally to Spain, Portugal, Germany, England, and differents parts of Italy.

COCCIÆ Pilulæ, in the *Materia Medica*. See Pills.

COCCIFEROUS, in *Botany*, ſuch plants or trees as bear berries. See Bacciferous.

COCCINELLA, in *Entomology*, a genus of coleopterous inſects, poſſeſſing, according to the ſyſtem of Linnæus, the following eſſential character: antennæ clavated, or ending in a club, which is ſolid and truncated; anterior feelers hatchet-ſhaped, poſterior filiform; thorax and wing-caſes margined; the body hemiſphærical, and the abdomen flat beneath. The Fabrician character of the coccinella conſiſts in having the anterior feelers hatchet-ſhaped, the poſterior filiform; lip cylindrical; and the antennæ terminating in a ſolid club.

This genus of inſects is divided into ſections according to the colour of the wing-caſes; and the ſpots, or dots with which they are marked. The firſt ſection comprehends thoſe which have the wing-caſes red or yellow, and marked with black dots; the ſecond, thoſe having the wing-caſes red or yellow, with white or whitiſh dots: the third has the wing-caſes yellow, ſpotted with red; the fourth, the wing-caſes black, with red ſpots; and the fifth, the wing-caſes black, dotted with white or yellow.

The coccinellæ are generally found on plants, and as they ſubſiſt chiefly on the aphides, or lice that infeſt vegetables, are to be numbered among thoſe inſects which are eſſentially ſerviceable to horticulture and agriculture. The larvæ of the coccinellæ, a lively race, are frequently ſeen running briſkly over plants in ſearch of the aphides, which they attack with ferocity, and devour in vaſt numbers. Theſe larvæ are of an elongated figure, becoming pointed towards the tail; the head is rather flat and protected by a ſcaly covering, but the reſt of the body is naked. This animal is furniſhed alſo with ſix legs, which, like the head, are of a ſcaly nature. The body conſiſts of twelve joints or annulations, and in ſome ſpecies is rough, with little verrucoſe, or wart-like puſtules. When in the pupa ſtate, the coccinellæ are enveloped in a thin and delicate membrane, and are attached to the under ſurface of the leaves of thoſe plants which they moſt commonly inhabit in the larva and fly ſtate. The pupæ of many ſpecies are elegantly dotted, and ſpotted with black, upon a ground of various colours. The inſects of this genus are, with few exceptions, of a ſmall ſize.

Species.

Firſt Diviſion. Thoſe with the wing-caſes red or yellow, and marked with black dots.

Cincta. Subrotund, yellowiſh, thorax with four black dots. Deſcribed by Fabricius in his Supplementum as a native of the Eaſt Indies, from a ſpecimen in the cabinet of Dald[illegible]ff.

9 Notata. Red, with nine black dots; margin of the head and thorax white. Herbſt. Inhabits North America.

Laeta. Red, with thirteen black dots; thorax black, with the margin and two dots white. Fabr. Suppl. Inhabits Mogadore.

Lineolata. Red, with five dots, and two little lines of black

black at the baſe of the wing-caſes. A new ſpecies taken by the Revd. Mr. Burrel, near Holt, in Norfolk. Marſh. Ent. Brit.

11-NOTATA. Red, with eleven black dots; margin of the wing-caſes at the baſe yellow, body black. Marſh. Ent. Brit. Diſcovered in Kenſington Gardens.

FLAVA. Wing-caſes, legs, and thorax at the ſides yellow. Marſh. Inhabits Britain.

SINUOSA. Wing-caſes fulvous, with two abbreviated ſinuous ſtripes, and a black dot each ſide. Marſh. Inhabits Britain.

MARGINATA. Wing-caſes red, with black margin; thorax with a white marginal dot each ſide. Linn. A native of South America.

LIMBATA. Black; diſk of the wing-caſes red, with two black dots. Fabr. Inhabits Hamburgh. This is of the middle ſize, and has the head and thorax black; and the wing-caſes black, with the diſk red, and marked with a large black dot each.

MARGINELLA. Wing-caſes dull teſtaceous, with yellow margin. Fabr. A native of America.

SURINAMENSIS. Wing-caſes red and immaculate; head and thorax black. Linn. *Erotylus Surinamenſis*, Olivier. Found in South America.

IMMACULATA. Wing-caſes ferruginous and immaculate; thorax black; margin and two dorſal dots white. Fabr. Inhabits American iſlands.

UNICOLOR. Thorax and wing caſes immaculate. Fabr. Deſcribed as a native of the Eaſt Indies, from the cabinet of Abildgard.

M. NIGRUM. Oblong, wing-caſes teſtaceous and immaculate; thorax white, with a black M. Fabr. Inhabits Kiel.

SANGUINEA. Wing-caſes ſanguineous and immaculate; thorax ſpotted with black. Linn. A ſpecies of ſmall ſize; found in South America.

IMPUNCTATA. Wing-caſes red, and without ſpots; thorax red, and browniſh in the middle. Deſcribed by Linnæus as a native of Sweden, where it inhabits gardens; it is found alſo in other parts of Europe, as Germany, Spain, and Britain. Paykul calls it *coccinella aptera*.

DIMIDIATA. Wing-caſes ſcarlet, with the tip black. Fabr. A native of Coromandel, in the Bankſian cabinet. This is of a large ſize, with the head and thorax rufous, and immaculate; wing-caſes with black future; body and legs yellowiſh.

MARGINE-PUNCTATA. Wing-caſes yellow, with whitiſh margin, and two black dots. Fabr.

This kind inhabits Saxony, according to Hybner; it is of a large ſize, with the head and thorax white, ſprinkled with many black dots; the wing-caſes are yellow, with pale ſpots.

LINEOLA. Wing-caſes red; ſmall line at the baſe, and the tip black. Fabr. A native of New Holland, in the Bankſian cabinet. This is of a ſmall ſize; the head is whitiſh; thorax whitiſh, with four black dots; body beneath black, and ſhanks of the legs white.

UNIFASCIATA. Wing-caſes red, with a black band in the middle. Fabr. Deſcribed as a native of Hamburgh from the collection of Dr. Schulz; it is alſo found in Britain. Marſh. This is of the middle ſize, with the head and thorax black, and without ſpots; near the ſcutel is a ſmall oblique black line; the body is black.

ANNULATA. Wing-caſes red, with ſubannular black ſpot. Linn. Inhabits Europe.

TRILINEATA. Wing-caſes yellow, with three abbreviated black lines. Fabr. An American ſpecies in the cabinet of Zſchuck. This is a ſmall inſect; the body is black; thorax deep black, with the exterior margin whitiſh; margin of the wing-caſes with a thin edge of black.

VITTATA. Wing-caſes yellow; margin, future, and two ſtripes in the middle black; thorax black, with the anterior margin white. Fabr. A native of Guinea.

STRIATA. Wing-caſes yellow, margin, future, and two abbreviated black ſtripes; thorax yellow, with two dull dots. Fabr. Inhabits the ſame country as the laſt.

OBLONGO-PUNCTATA. Wing-caſes yellow; with four abbreviated lines, and ſix dots of black. Fabr. A native of Ruſſia. A large ſpecies.

ABBREVIATA. Wing-caſes red; an abbreviated band behind, and two dots of black; thorax black, with two white lines. Fabr.

This is deſcribed from the cabinet of Dr. Blagden as a native of North America. The body is oblong and black; front with a large white ſpot.

6-LINEATA. Wing-caſes yellow, with ſix lines, and three dots of black. Fabr. A native of Ruſſia. This is of a large ſize, the colour black; head with two white dots at the baſe; exterior margin of the thorax white, with a black dot.

2-PUNCTATA. Wing-caſes red, with two black dots. Linn. A ſpecies very common in gardens in Europe.

3-PUNCTATA. Wing-caſes red, with three black dots. Linn. A native of Germany, and parts of Europe.

HIEROGLYPHICA. Wing-caſes yellow, with two longitudinal ſinuous ſpots of black. Linn. Inhabits Europe.

RIVULARIS. Wing-caſes yellow, with two ſinuous dorſal bands, and ſix dots of black; thorax black, with two yellow dots. Fabr. *Coccinella tranſverſalis*. Thunberg. Inhabits Sweden.

TRICINCTA. Ovate; wing-caſes red, with three black bands, the anterior one abbreviated and tricuſpidate. Fabr. A native of China. This is of a moderate ſize and black colour. The thorax is black and ſhining with a white marginal ſpot each ſide.

ARCUATA. Ovate; wing-caſes red, with four dots, two bands, and dot at the tip black. Fabr.

Deſcribed from the cabinet of Scheſtedt as a native of China. This is of the middle ſize. The body is black; head whitiſh; thorax black, with the anterior part of the margin, and ſides whitiſh; future of the wing-caſes black.

UNDATA. Oblong; wing-caſes pale yellow; flexuous band and two dots black; thorax dotted with yellow. Fabr. Inhabits the Cape of Good Hope. Bankſian cabinet.

The body of this ſpecies is large, oblong, and black; head with two frontal yellow ſpots; thorax with three dorſal ſpots, margin, and mark extending from the baſe of the margin yellow; future of the wing-caſes black; legs yellow; joints black.

FLEXUOSA. Ovate; wing-caſes pale yellow; flexuous band, and two dots black; margin of the thorax white. Fabr. Inhabits Europe.

CINGULATA. Wing-caſes pale yellow; with four dots at the baſe, poſterior band and dot at the tip black. Fabr. A native of Tranquebar. Hybner.

INAEQUALIS. Wing-caſes yellow, with three anterior dots, future, and band at the tip black. Fabr.

This ſpecies is deſcribed from the Bankſian cabinet; it is an inſect of the middle ſize, and inhabits New Holland. The body is black; head yellow, and thorax black, with the fore part yellow.

TRIFASCIATA. Wing caſes red, with three abbreviated black bands. Linn. Found in gardens in Europe.

INTER-

Interrupta. Wing-cases yellow, with two waved interrupted bands, and two posterior dots of black. Fabr. Native country unknown.

2-Fasciata. Wing-cases ferruginous, with two bands and four dots of black. Fabr. Described by Thunberg under the name of *coccinella flexuosa*. It is a native of the Cape of Good Hope.

4-Notata. Wing-cases red, with four black dots at the base; margin of the thorax white. Fabr.

Inhabits Europe. The head and anterior parts of the thorax with the sides whitish; legs testaceous.

4-Maculata. Wing-cases red, with four black dots; thorax black, with a marginal white spot. Hybner. A native of Saxony.

The head of this species is black with two pale dots at the base; thorax black, shining, with the marginal spot large.

5-Punctata. Wing-cases sanguineous, with five black dots. Geoffr. A very common species in Europe.

5-Maculata. Oblong; wing-cases yellowish, with five black dots; thorax black with three rays of white on the anterior margin. Hybner. Found in Saxony and other parts of Europe. The body is large and oblong; anterior parts of the head white with two black dots.

6-Punctata. Wing-cases red, with six black dots. Linn.

Inhabits gardens in Europe. An insect of small size; the head is black with two white dots; thorax black, with the margin and two dorsal dots white.

Glacialis. Wing-cases red, with six dots of black, the intermediate one sinuate, and larger. Fabr.

A native of North America. The head is black, with the frontal spot white.

6-Maculata. Wing-cases red, with six black dots, the four anterior ones sinuate and transverse. Fabr.

An inhabitant of the East Indies, described from a specimen in the Banksian cabinet. The head is whitish; anterior part of the thorax white, with black spots; body pale yellow.

7-Punctata. Wing-cases red, with seven black dots. Linn.

Common in most parts of Europe. Donov. Brit. Inf. Known in England by the name of *lady-bird*, and *lady-cow*. In its manners of life it differs in no respect from the other species of the same natural family.

7-Maculata. Oblong; wing-cases red, with seven black dots; the middle one on the suture three lobed. Fabr.

Inhabits Germany according to Dr. Schulz. The head is black; thorax black, with the anterior and lateral margin white; body white.

7-Notata. Oblong: wing-cases red, with seven black dots; margin of the thorax and two dots in the middle white. Fabr. *Coccinella mutabilis*, Paykul.

Inhabits gardens in Germany; and is found in England, but not commonly. This insect is of a small size. The head is white, with black posterior margin; thorax black, glossy, with the margin in front and at the sides white; body black.

8-Punctata. Wing-cases red, with eight black dots; thorax white, with black dots. Linn.

A native of the north of Europe. The head is whitish, with two frontal black dots.

Transversalis. Wing-cases yellow, with eight black spots, the four anterior ones sinuate. Fabr.

Inhabits Coromandel. Banksian cabinet. The thorax is black and glossy, with a white spot each side at the tip; suture of the wing-cases and body black.

8-Maculata. Wing-cases pale yellow, with eight black dots; the six anterior ones transverse and sinuate. Fabr.

Same cabinet as the preceding; the country is unknown. The body of this insect is dull yellow, the eyes black; suture of the wing-cases black; body black.

9-Maculata. Wing-cases red, with nine black dots, the posterior one common; thorax with two dots.

A native of New Holland, in the Banksian cabinet; the body is rufous; thorax rufous, with two black dorsal dots.

9-Punctata. Wing-cases red, with nine black dots. Linn.

Found in gardens in Europe; in England not frequent. Paykul describes this species under the name of *coccinella collaris*.

10-Punctata. Wing-cases fulvous, with ten black dots; thorax with four spots. Degeer, &c.

This species inhabits Europe. The head is black, with a tridentated white spot in front; thorax, with four whitish spots. It is found chiefly in gardens.

Innuba. Oblong; wing-cases testaceous, with ten black dots; thorax immaculate. Fabr. A native of India.

Dilatata. Subrotund; wing-cases margined with fulvous, and marked with ten black dots; thorax with two dots.

Inhabits America. It is of a large size, and fulvous; anterior part of the thorax emarginate; the margin of the wing-cases dilated and black.

11-Punctata. Wing cases red, with eleven black dots; body black. Linn.

Found principally in the northern parts of Europe; occurs occasionally in Britain.

12-Punctata. Wing-cases yellow, with twelve black dots; the outer one linear, and repandate. Linn.

Inhabits gardens in Europe. The thorax is yellow, with dots, and two spots of black.

Variegata. Wing-cases yellow, with twelve dots, and two bands of black in the middle.

Described from the Banksian cabinet. The head is yellow, with the eyes black; thorax yellow, with five black dots at the base. It is a native of the Cape of Good Hope.

Crysomelina. Wing-cases rufous, with twelve black dots; thorax immaculate.

An African species, found on the *cactus opuntia*, and first described by professor Thunberg. The head and thorax are red, with the margin rather paler; dots on the wing-cases disposed in pairs; legs yellowish.

Cassidea. Oblong, red; wing-cases with twelve dots of black, and on the thorax four. Inhabits Maryland.

13-Maculata. Wing-cases yellow, with thirteen black dots; body orbicular. Forster. Nov. Sp.

Described as a native of Sweden. The thorax is white, with four black dots. This species has been found in Germany, according to Panzer, and also in England. Marsham, &c.

13-Punctata. Body pale yellow, with thirteen black dots; body oblong. Linn. Inhabits gardens in Europe.

Versicolor. Wing-cases yellow, with fourteen black dots, two of which are common. Fabr.

A native of China. The body is large and orbicular; the head is yellow; thorax margined, yellow, with a black spot in the middle.

14-Maculata. Wing-cases yellow; suture, and fourteen spots black. Hybner. Inhabits Saxony.

14-Punctata. Reddish, with fourteen black dots. Linn.

A native of Europe. Found in England, not uncommon.

Donov.

Donov. Brit. Inf. &c. *Coccinella conglomerata* of Fabricius.

16-Punctata. Wing-cafes yellow, with fixteen black dots; head with four black dots.

Inhabits Italy. This fpecies is of a large fize; its figure oblong; the head is white, with four black dots; thorax white, with many approximate dots.

18-Punctata. Wing-cafes yellow, with eighteen black dots, the laft arched. Linn.

Inhabits the northern parts of Europe. This is of the middle fize, and has the fides of the thorax yellow.

19-Punctata. Wing-cafes yellow, with nineteen black dots. Linn. Found on plants in Europe.

20-Punctata. Wing-cafes yellow, with twenty black dots. Geoffr.

Defcribed by Fabricius as a native of England, on the authority of a fpecimen in the cabinet of Mr. Aiton.

22-Punctata. Wing-cafes red, with twenty-two black dots. Linn. Inhabits gardens in Europe.

22-Maculata. Ferruginous; wing-cafes yellow, with twenty-two black dots. Fabr.

A native of Guinea, in the cabinet of Ifert. This is of a large fize; the head and thorax are dull ferruginous, glabrous, and immaculate; body yellow, abdomen in the middle ferruginous.

23-Punctata. Wing-cafes red, with twenty-three diftinct black dots. Linn. Found in gardens in Germany.

24-Punctata. Wing-cafes red, with twenty-four black dots. Linn. Inhabits Europe, and is found in England.

24 Maculata. Ferruginous; wing-cafes with twenty-four black dots. Fabr.

A native of Tranquebar. This is of a large fize, and gibbous. The head is ferruginous and immaculate: thorax ferruginous, with black dots; legs ferruginous, with a black fpot on the thighs.

28-Punctata. Wing-cafes red, with twenty-eight black dots. Fabr.

Inhabits the fame country as the laft. Difcovered by Dr. Koenig.

Conglobata. Wing-cafes yellow; with numerous contiguous black dots; the tip immaculate. Linn. *Coccinella rofea*, Degeer. *Coccinella gemella*, Herbft. A native of Europe.

Lineola. Wing-cafes yellowifh, with two little lines, and fomewhat contiguous fufcous dot. Fabr.

Inhabits South America. This is of a fmall fize. The head is white, with the eyes black; body and legs white.

Tricolor. Wing-cafes yellow, with ten red dots, and ten marginal black fpots. Inhabits Amfterdam ifland. Bankfian cabinet.

Crux. Wing-cafes yellow, with two black lines and crofs. Thunberg. Inhabits the Cape of Good Hope.

Comma. Wing-cafes yellow, with black future, margin, and line. Thunberg. An African fpecies.

Second Divifion. Wing-cafes red or yellow, with white, or whitifh dots.

Biguttata. Wing-cafes rufous, with two yellow dots.

A fpecies of fmall fize found in Europe. The thorax is black, with the lateral edge yellow.

8-Guttata. Wing-cafes red, with eight yellow dots. Thunberg. A native of Japan.

Strigata. Wing-cafes rufous, with an abbreviated whitifh ftreak. Fabr. Suppl.

2-Guttata. Wing-cafes rufous, with two yellow fpots.

Defcribed by Fabricius from the Hunterian collection. It is of a fmall fize; the thorax black, glabrous, with the lateral margin yellow. A native of Europe.

10-Guttata. Wing-cafes yellow, with ten white dots. Linn.

A native of Sweden, according to Linnæus; found alfo in England. Vide Donov. Brit. Inf.

Bis-6 Guttata. Wing-cafes fulvous, with twelve white dots, and the thorax edged with white. Fabr. Inhabits Norway.

Cayennensis. Wing-cafes fulvous, with twelve white dots, and two connected white lunules on each fide. *Coccinella 12-guttata*, Fabr.

Found in Cayenne. The thorax is rufous, with a large white fpot on each fide.

14-Guttata. Wing-cafes rufous, with fourteen white dots. Linn. A native of Europe; and inhabits Britain.

Bis-7-Guttata. Wing-cafes fulvous, with fourteen white dots; margin of the thorax white. *Coccinella 14-guttata*, Schall. Act. Hall. A native of Germany.

15-Guttata. Wing-cafes yellow, with fifteen white dots. Herbft, &c. A native of Germany.

16-Guttata. Wing cafes red, with fixteen white dots. Linn.

Inhabits England, and other parts of Europe. Donov. Brit. Inf.

18-Guttata. Wing-cafes red, with eighteen white dots, the firft two lunate.

Defcribed as a native of Europe by Linnæus and Schæffer. Inhabits Germany. Panzer. Rarely found in England, once taken near Barton by Mr. Sheppard. Vide Marfh. Ent. Brit.

20-Guttata. Wing-cafes red, with twenty white fpots. Linn. Found in gardens in Europe.

Oblongo Guttata. Wing-cafes red, with lines and dots of white. Linn.

Inhabits pines in Europe, and is a rare fpecies. This is an elegant fpecies, and has been difcovered in England. Donov. Brit. Inf.

Third Divifion. Wing-cafes yellow, fpotted with red.

Obliterata. Wing-cafes yellow, with four rufous dots; the anterior pair obfolete. Thunberg. Inhabits Upfal. Act. Upf. 4. t. i. f. i.

Fourth Divifion. Wing-cafes black, with red fpots.

7-Pustulata. Wing cafes black, with feven red dots. Marfh.

The head is black, with two yellow lines between the eyes; thorax black, with the anterior margin yellow. Inhabits England.

10-Pustulata. Wing-cafes black, with ten fulvous dots. Linn.

Inhabits gardens in Europe. *Coccinella variabilis* of Paykul.

Bimaculata. Downy; wing-cafes black, with two rufous fpots. Marfh.

Found in England. The antennæ and mouth is rufous; body black; legs rufous, with black thighs.

Biliturata. Downy, head ferruginous; wing-cafes black, with two ferruginous blotches; legs teftaceous. Marfh. A native of Britain.

Fulvifrons. Deep black, front fulvous. Marfh. Inhabits England.

Rufipes. Wing-cafes black, with a large marginal fpot, and legs rufous. Fabr. Suppl.

Inhabits the South of Europe. The body is fmall and ovate; head and thorax black and immaculate; legs entirely rufous.

Impustulata. Wing cafes black and immaculate. Linn. Inhabits the woods of Germany.

Nitidula.

Nitidula. Wing-cafes braffy-black; thorax margined with rufous. Fabr.

Found in the American iflands. It is a fmall infect; the head is black and immaculate, and the body rufous.

Parvula. Wing-cafes black; head, thorax and legs rufous. Geoffr. Inhabits the environs of Paris.

Villosa. Villous and black; the margin of the wing-cafes yellow. Fabr.

A native of Cayenne, in the cabinet of Don Rohr.

Analis. Wing-cafes black, with the tip red and immaculate. Hybner.

A native of Saxony. The head is red, and without fpots; thorax rufous, and at the bafe in the middle black; abdomen and legs rufous.

Hæmorrhoidalis. Wing-cafes black; the tips red, with a black band. Fabr. Inhabits Hamburgh. Dr. Schulz.

Oculata. Wing-cafes black, with two red fpots; a large marginal white fpot on each fide the thorax. Fabr.

This is a native of North America, and is allied to *Coccinella cacti*, but is rather lefs.

Cacti. Wing-cafes black, with two rufous fpots, and the thorax immaculate. Linn. Inhabits America.

Variabilis. Wing-cafes black, with two lunate fubmarginal red fpots. Fabr. *Coccinella auftriaca*, Schrank. Found in the neighbourhood of Hamburgh.

Frontalis. Wing-cafes black, with two red fpots; front, and anterior legs black. Fabr. A native of Saxony.

4-Pustulata. Wing cafes black, with four red dots; orbits of the eyes, and edge of the thorax pale. Linn. Inhabits Europe.

4-Verrucata. Wing-cafes black, with four red fpots; tail rufous. Fabr. Inhabits Kiel.

Bis-2-Pustulata. Wing-cafes black, with four red dots; head and thorax dull black. Fabr.

An European fpecies, and is fometimes found in England.

Erythrocephala. Wing-cafes black, with fix red dots; head and margin of the thorax pale reddifh. Fabr. Found in Kiel.

6-Pustulata. Wing-cafes black, with fix red dots; body black. Linn.

Inhabits gardens in Europe, and is found in England. Vide Donov. Brit. Inf.

Lunata. Wing-cafes black, with ten red fpots, fix of which are lunated. Fabr.

Defcribed from a fpecimen in the Bankfian cabinet, that was found in St. Helens.

Fifth Divifion. Wing-cafes black, dotted with yellow or white.

10-Pustulata. Wing-cafes black, with twelve white dots; the exterior ones connected at the margin. Fabr. A native of Europe.

14-Pustulata. Wing-cafes black, with fourteen white dots. Linn. Found on plants in Europe.

Guttato-Pustulata. Wing-cafes black, with two yellow fpots and four rufous ones.

Defcribed from the Bankfian cabinet as a native of New Holland.

Felina. Wing-cafes black, with fix white dots; body globular. Fabr.

An American fpecies. This is of a fmall fize; the head is white; thorax white, with a black fpot at the bafe.

Pantherina. Wing-cafes black, with eight yellow dots. Linn. Inhabits Europe.

Pardalina. Wing-cafes black, with ten dots, and finuate margin white.

Defcribed from a fpecimen in the Bankfian cabinet. The native country unknown.

Ursina. Wing-cafes black, with ten white dots; and the head and anterior margin of the thorax white. Fabr. A native of North America, in the Hunterian collection.

Leonina. Wing-cafes black, with fixteen white dots.

An inhabitant of New Holland, defcribed by Fabricius from the Bankfian cabinet.

Tigrina. Wing-cafes black, with twenty white dots; thorax fpotted. Linn. An European fpecies.

Canina. Wing-cafes black, with twenty black dots; head and thorax villous and immaculate. Fabr. A native of the Cape.

Thunbergii. Wing-cafes black, with the margin and two dots white; head black, with white dots. Thunberg. Inhabits Upfal.

Flavipes. Wing-cafes black; thorax black, with two yellow dots; margin of the thorax with the tail yellow. Thunberg. Inhabits the Cape.

Villosa. Villous, black; margin of the fhells yellow. Thunberg. Inhabits Cayenne.

Lævis. Wing-cafes black, with fix yellow dots; anterior angles of the thorax yellow. Thunberg.

Dentata. Wing-cafes black; the outer margin, tridentated line, and fix dots yellow. Thunberg. A native of the Cape.

COCCIUM, or Coccio, in *Ancient Geography*, a place in the ifle of Albion, placed in Antonine's Itinerary on the route from Glanoventa to Mediolanum, between Bremetanacis and Mancunium; fuppofed to be Rilchefter.

COCCO, the name of a plant in the Weft Indies, and in fome of the iflands of the South Sea, called alfo *Indian kale.*

COCCOCYPSELUM, in *Botany* (from κοκκος, a *grain*, or *feed*, and κυψελη, or κυψελιον, a *cheft* or *veffel.*) Schreb. 1721. Mart. Willd. 207. Lam. Illuft. 168. Juff. 198. (Cocipfele, Encyc.) Clafs and order, *tetrandria monogynia.* Nat. Ord. *Rubiaceæ*: Juff.

Gen. Ch. *Cal.* Perianth fuperior, one-leafed, four-cleft, permanent; fegments linear-lanceolate, erect. *Cor.* Monopetalous, funnel-fhaped; tube longer than the calyx; border four-cleft, fegments egg-fhaped, half-open. *Stam.* Filaments four, fhort, inferted into the tube; anthers oblong, erect. *Pift.* Germ inferior, roundifh; ftyle the length of the corolla, bifid at the top; ftigmas oblong. *Peric.* Capfule fucculent, Juff. La Marck; Ill. (berry; Schreb. Lam. Encyc. Willd.) inflated, roundifh, crowned with the calyx, two-celled. *Seeds* numerous, fmall, compreffed, affixed to the partition.

Eff. Ch. Calyx fuperior, four-cleft. Corolla funnel-fhaped. Capfule (or berry) inflated, crowned, two-celled, many-feeded.

Sp. 1. C. *repens*, Mart. Willd. Swartz. Prod. 31. C. herbaceum; Lam. Ill. Pl. 64.—Herbaceum repens; Browne Jam. 144. tab. 6. fig. 1. " Stem creeping at the bafe; leaves egg-fhaped; cymes axillary, nearly feffile." Lam. *Stems* growing in tufts; each of them creeping eighteen or twenty inches from the root, and fhooting out a few lateral branches as it runs. *Leaves* oppofite. *Flowers* and *fruit* on fhort, divided peduncles from alternate axils. Browne. A native of Jamaica. 2. C. *virgatum*, Lam. Ill. (Naciboea alba; Aubl. tab. 37. fig. 2.) " Stems rod-like; leaves acuminate; cymes lateral, peduncled; peduncles longer than the petiole." Lam. A native of South America, communicated by M. Richard.

C. *uniflorum*, and *biflorum*; Willd. See Fernelia *buxifolia*.

We confefs that we are rather inclined to think with Willdenow, that there is no folid generic diftinction between coccocyp-

coccocypſelum and fernelia. For it appears to us that a ſucculent capſule, without valves, would be better called a dryiſh berry (bacca vix carnoſa), the character attributed to the fruit of fernelia. But as the two genera are kept diſtinct by Juſſieu, who muſt have had both of them in immediate contemplation, when he drew up the third ſection of his natural order, *rubiaceæ*, we have not choſen to diſſent from ſuch high authority. The only remaining differences are, that in fernelia the partition is perforated in the middle, and the ſeeds are attached to a central receptacle which ſupplies the defect. Willdenow, however, is wrong in his appropriation of La Marck's figures; for on the authority of La Marck himſelf, in his Illuſtrations, fig. 1 is not buxifolia, but his own obovata, and fig. 2. is his lygiſtum axillare, copied from Browne's tab. 3, fig. 2, and engraved by miſtake as a fernelia. The new genera coccocypſelum, lygiſtum, and fernelia, as well as the petesia of Linnæus, ſeem to need a more accurate inveſtigation; and it will probably be found, that no violence would be done to nature if they were all united into one.

COCCODES, in *Natural Hiſtory*, a name given by Mercatus to thoſe ſtones of the AMMITES kind, whoſe grains are very large.

COCCOLOBA, in *Botany*, (ſo called from the kernel being lobed at the bottom.) Linn. Gen. 496. Schreb. 678. Willd. 786. Gært. 261. Juſſ. 82. Vent. 2. 249. (Coccolobis; Brown. Raiſinier: Encyc.) Claſs and order, *octandria trigynia*. Nat. Ord. *Holoraceæ*, Linn. *Polygoneæ*, Juſſ. Vent.

Gen. Ch. *Cal.* Perianth one-leafed, five-cleft; ſegments oblong, obtuſe, concave, coloured, ſpreading widely, permanent. *Cor.* none. *Stam.* Filaments eight, awl-ſhaped, ſhorter than the calyx: anthers roundiſh, didymous. *Piſt.* Germ egg-ſhaped, three-ſided; ſtyles three, ſhort, ſpreading; ſtigmas ſimple. *Peric.* the permanent calyx, thickened into a berry, involving the ſeed. (Drupe; Gært.) *Seed*; nut, egg-ſhaped, acute, one-celled.

Eſſ. Ch. Calyx five-cleft, coloured, corolla none. Nut covered by the calyx, which is converted into a berry.

Sp. 1. C. *uvifera*. Linn. Sp. Plant. 1. Mart. 1. Poir. 1. Willd. 1. Lam. Ill. tab. 316. fig. 2. Gært. tab. 45. Jacq. Amer. 112. tab. 73. Brown. Jam. 208. (Polygonum caule arboreo. fructibus baccatis; Linn. Sp. Pl. Ed. 1. Uvifera; Hort. Cliff. Pluk. Alm. tab. 236, fig. 7. Guajabera; Plum. ic. 145. Populus americana rotundifololia; Bauh. Pin. 430. Prunus; Sloan. Jam. 183. Hiſt. 2. tab. 220, fig. 3. Cates. Car. 2. tab. 96.) Round-leaved ſea-ſide grape, or mangrove grape tree. "Leaves heart-ſhaped, roundiſh, ſhining." A large tree. *Branches* irregularly ſpreading, not forming a handſome head, but rendered beautiful by the leaves and fruit; bark cinereous, thin; in the young trees ſmooth; in the old ones full of chinks; wood hard, ponderous, red; but of little uſe, except for burning, on account of its fibrous texture. *Leaves* large, alternate, entire, generally ending in a ſhort blunt point, but often quite round, thick, coriaceous, deep green, with alternate prominent nerves, connected by ſmall ſcarlet veins; petioles hard, ſhort, thick; ſtipules ſheathing the branches. *Flowers* whitiſh, very ſmall; racemes about a foot long, ſimple, terminal, ſolitary, thick, upright at the time of flowering, pendulous with the ripe fruit; pedicels one-flowered, thick, ſhort. *Berries*, the ſize of a ſmall cherry, roundiſh, umbilicated, conſiſting of a purpliſh membrane, which covers a ſoft, thin, not unpleaſantly aſtringent, pulp, and a large three lobed nut. Linn. *Drupe* formed of the berried calyx, becoming black and wrinkled when ripe; pulp ſoft, drying into a thin cruſt; ſhell thin, like paper, intimately united with the pulp, half three-celled; partitions membranous, narrow, to be found only at the bottom of the drupe. *Receptacle* a ſmall fungous tubercle, formed at the baſe of the fruit by the concurrence of the partitions. *Seed* ſingle, ſomewhat globular, acuminate at the top, deeply umbilicated at the bottom, ſtriated with wrinkles, ferruginous brown. Gært. A native of South America and the Weſt Indies, on a ſandy ſoil, generally near the ſea. The fruit is ſold in the market, and forms part of the deſert in its native countries. 2. C. *latifolia*. Poir. 2. Lam. Ill. Pl. 316. fig. 4, a leaf. "Leaves entire, very broad, contracted at the baſe." In habit reſembling the preceding, but differing remarkably in its leaves. Young branches ſmooth, finely ſtriated, a little compreſſed. *Leaves* thin, rather membranous than coriaceous, ſmooth, quite entire, at leaſt as broad as long, narrowed, not heart-ſhaped at the baſe; with lateral ſimple yellowiſh nerves, which are connected by capillary reticulated veins. A native of South America, cultivated in the botanic garden at Paris, where it has not yet flowered. 3. C. *auſtralis*. Mart. 12. Poir. 16. Willd. 2. Forſt. Prod. n. 176. "Leaves cordate-ovate, acute; flowers polygamous." A native of Zealand. From the drawing in ſir Joſeph Banks's collection, it ſeems to be a polygonum. 4. C. *pubeſcens*. Linn. Sp. Pl. 2. Mart. 2. Poir. 3. Willd. 3. Brown. Jam. 210. (C. grandifolia; Jacq. Amer. 113. Scortea; Pluk. Phyt. 222. fig. 8.) "Leaves orbicular, pubeſcent." A tree ſixty or eighty feet high. *Trunk* rough. *Branches* only two or three principal ones, but little ſubdivided, thick, ſpreading. *Leaves* alternate, very large, ſometimes two feet in diameter, quite entire, ſlightly heart-ſhaped, much veined and wrinkled, ſmooth when old; petioles hard, thick, very ſhort, ſheathing at the baſe. *Flower* and *fruit* unknown in Europe. A native of the Weſt Indies. The wood, according to Jacquin, is of a deep red colour, very hard, heavy, brittle, but almoſt incorruptible: when uſed for poſts or paliſades, the part under ground becomes as hard as ſtone. The fruit is ſaid to be good to eat. 5. C. *diverſifolia*. Poir. 4. Willd. 4. Jacq. Amer. 114. tab. 76. "Leaves of the branchlets ovate; of the branches ovate-heart-ſhaped." A ſhrub, ten or twelve feet high. *Leaves* alternate, petioled, a little coriaceous, quite entire, ſlightly wrinkled, ſhining, veined, ending in an obtuſe point. *Racemes* about three inches long, terminal, upright, ſimple, ſolitary. *Fruit*, about the ſize of a ſmall cherry, nearly round, almoſt umbilicated at the ſummit by the union of the thick fleſhy leaves of the calyx; pulp ſoft, of a beautiful purple colour, a little more acid than that of C. uvifera, but eaten by peaſants and children. A native of St. Domingo. 6. C. *flaveſcens*. Mart. 7. Poir. 5. Willd. 5. Jacq. Amer. 114. tab. 75. "Leaves elliptical, obtuſe, mucronate, heart-ſhaped at the baſe." Willd. A ſmall branching tree or ſhrub, about twelve feet high. *Leaves* alternate, coriaceous, ſhining, quite entire, on very ſhort petioles. *Racemes* ſcarcely an inch and a half long, terminal, ſimple, erect. *Fruit* roundiſh, purple, a little larger than a pea; pulp reddiſh, ſweet and eatable, but not much eſteemed. A native of St. Domingo. 7. C. *excoriata* Linn. Sp Pl. 4. Mart. 3. Poir. 6. Willd. 6. (C. cortice lævi; Brown. Jam. 210. Guajabara; Plum. Ic. 146. fig. 1. Arbor indica; Pluk. Amath. tab. 353. fig. 4. ?) "Leaves egg-ſhaped; branches appearing as if ſtripped of their bark." Linn. "Leaves oblong-egg-ſhaped, rather acute, heart-ſhaped at the baſe; racemes pendulous." Willd. A lofty tree. *Branches* with a very thin, even-ſurfaced bark. *Leaves* alternate, on ſhort petioles, coriaceous, entire, ſmooth, green above, yellowiſh underneath, finely nerved and veined; ſtipules embracing the ſtem. *Racemes* long. A native of America and the Weſt Indies. 8. C. *nivea*. Mart. 4. Poir. 7. Willd. 7. Swartz, Prod. 64. Flor. ind. occid. vol. ii. p. 693. Jacq. Amer. 115. tab. 78. "Leaves oblong, acuminate, veined, ſhining above;

 racemes

racemes almost erect." A tree about twenty feet high, erect, branched. *Leaves* alternate, half a foot long, entire, petioled, wrinkled, thin, membranous. *Flowers* small, yellowish; racemes terminal, solitary, simple, calyx finally thick, succulent, of a snow-white colour, covering to the middle a three-sided, black, shining nut. *Fruit* sweet and pleasant. A native of the West Indies. 9. C. *leoganensis*. Mart. 5. Jacq. Amer. 113. tab. 178. fig. 33. (C. uvifera. β. Poir. Willd.) "Leaves roundish, quite entire, shining, flat; racemes erect." A shrub ten feet high. *Leaves* resembling those of C. uvifera, but only half the size. A native of Port-au-Prince and Leogane in St. Domingo. 10. C. *punctata*. Linn. Sp. Pl. 3. Mart. 8. Poir. 8. Willd. 8. (C. coronata; Jacq. Amer. 114. tab. 77. uvifera arbor; Pluk. Almag. 394. tab. 237. fig. 4.) "Leaves lanceolate, egg-shaped." A shrub, twelve or fifteen feet high, erect, branched. *Leaves* half a foot long, petioled, flat, quite entire, a little coriaceous, alternate, veined, shining, commonly two or three on each flowering branchlet; stipules sheathing. *Flowers* white; racemes scarcely an inch and a half long, erect, simple, terminal, solitary. Almost the whole receptacle, with a small part only of the calyx, becomes a roundish, dotted drupe, of a dark red colonr, and a sweetish, but rather austere taste. A native of South America, about Carthagena. 11. C. *obtusifolia*. Mart. 6. Poir. 12. Willd. 9. Jacq. Amer. 114. tab. 74. "Leaves oblong, very obtuse." A shrub, ten or twelve feet high, much and diffusely branched. *Branches* smooth, cinereous. *Leaves* narrow, elliptical, alternate, petioled, numerous, quite entire, shining, coriaceous, rounded at both ends, handsomely veined. *Flowers* white, small; racemes terminal, often alternate on the young branches, solitary, simple; calyx-leaves finally succulent, enveloping almost to the summit a shining nut, and leaving the upper part naked. *Fruit* astringent. A native of South America about Carthagena, in hedges and woods. 12. C. *microstachya*, Willd. 10. Poir. 13. "Leaves egg-shaped, obtuse, quite smooth; racemes nodding." *Branches* cylindrical, smooth, cinereous. *Leaves* at least an inch and a half long, alternate, petioled, broadest on one side, quite entire. *Flowers* small, in very short terminal racemes. A native of the West Indies. 13. C. *emarginata*. Murray Syst. Veg. 314. Mart. 9. Poir. 11. Willd. 11. Jacq. Amer. 314. Obs. vol. i. p. 18. tab. 9. "Leaves coriaceous, roundish, deeply emarginated." *Branches* somewhat zig-zag. *Leaves* alternate, petioled, entire, heart-shaped at the base, emarginate commonly with an acute angle, nerved and veined. *Fructification* unknown. A native of the West Indies. 14. C. *barbadensis*. Mur. Syst. Veg. 379. Mart. 10. Poir. 10. Willd. 12. Jacq. Amer. 37. Obs. 1. 18. tab. 8. "Leaves cordate, ovate, undulated." A tree. *Leaves* very large, petioled, simple, entire, acuminate, smooth on both sides, nerved, veined. *Fructification* unknown. A native of Barbadoes and Jamaica. 15. C. *tenuifolia*. Linn. Sp. Pl. 5. Mart. 11. Poir. 9. Willd. 13. Lam. Ill. tab. 316. fig. 1 and 3. Brown. Jam. 210. tab. 14 fig. 3. "Leaves egg-shaped, membranous." A shrub of humbler growth than any of the former. *Leaves* alternate, petioled, smooth, entire, obtuse, sometimes a little acute, thin; petioles, according to Linnæus, surrounded with a membrane instead of a stipule; but the specimens in La Marck's herbarium have sheathing stipules. *Flowers* scattered, pedicelled, in simple terminal racemes. A native of the West Indies. 16. C. *Asiatica*. Mart. 13. Lour. Coch. 239. "Climbing; leaves oblong, egg-shaped, veined; racemes terminal." *Stem* somewhat shrubby, branched. *Leaves* alternate, rather acuminate, quite entire, coriaceous. *Flowers* white, in loose racemes; calyx bell-shaped; style cloven half way down; stigmas roundish. *Fruit* a roundish five-lobed berry, formed from the five segments of the calyx, blackish, pellucid, small. A native of Cochin-china in hedges and woods. 17. C. *cymosa*. Mart. 14. Lour. Cochin. 240. "Climbing; flowers axillary and terminal, in sessile cymes." Exactly similar to the preceding, excepting the inflorescence; and like it, a native of Cochin-china.

Propagation and Culture. None of these species have produced either fruit or flowers in England: but are easily propagated by seeds imported in a perfect state. These should be sown in small pots filled with earth from the kitchen-garden, and plunged into a hot-bed. The plants will appear in five or six weeks, and in about a month after will be fit to transplant into separate pots; after which they must be constantly kept in the bark stove, and treated like other tropical plants.

COCCONAGÆ, in *Ancient Geography*, a people of India, on this side of the Ganges, according to Ptolemy.

COCCONAGARA, or COCCORANAGARA, a town of the Sines, according to Ptolemy, who were placed by the ancients in the southern parts of China.

COCCONAGI, islands situated at the entrance of the Red sea, towards the south of Arabia, according to Ptolemy.

COCCONILEA, in *Botany*, Bauh. Pin. Clus. See RHUS *cotinus*.

COCCOS, Gært. See COCOS.

COCCOTHRAUSTES, formed from κοκκος, a grain or kernel, and θραυω, to break, in *Ornithology*, the name of a very remarkable bird, considerably larger than the chaffinch, very short-bodied, and large beaked, whence it is called in English, the *gross-beak*, or *hawfinch*, the LOXIA *Coccothraustes* of Linnæus and Gmelin; the specific character of which is, that it has a white line on the wings, that the middle quills of the wings are rhomboid-shaped at the tips, and that the quills of the tail are black on the thinner side of the base. It is the *Gros-bec* of Buffon. Its head is very large in proportion to its body, and its great beak tapers from a very thick base to a sharp point, resembling the shape of a funnel. The upper mandible is cinereous, but of a lighter tint near the base; the lower mandible is cinereous at the edges, which close into the upper; its under side is flesh-coloured, with a cinereous cast. The tongue is fleshy, small, and pointed; the gizzard is very muscular, preceded by a pouch, containing in summer bruised hemp seeds, green caterpillars, almost entire, and very small stones. It is an inhabitant of the temperate climates from Spain and Italy as far as Sweden, and lives generally in the woods and mountains all summer; in winter it comes into the flat country, and resorts near the hamlets and farms. It is never seen in England, except in the winter months; it feeds on the kernels in the stones of fruit, as cherry-stones, and the like, and breaks these with great dexterity, whence its name; it will also eat the seeds of many different plants. This bird is solitary, shy, and silent; its ear is insensible, and its prolific powers are inferior to those of most other birds, so that the species is not numerous. The male and female are of the same size, and much resemble each other.

COCCOTHRAUSTES *cristata*, the name by which naturalists call the bird usually known among us by the name of the *Virginian nightingale*, it being truly a coccothraustes, though called by the improper name nightingale. Ray. See LOXIA *cardinalis*.

COCCULÆ, in *Botany*, *officinales*, Bauh. Pin. See CISSAMPELOS *cocculus*.

COCCULUS *indicus*. See CISSAMPELOS *cocculus*, and MENISPERMUM.

COCCUS, in the *Writings of the Ancients*, a name given by by ſome authors to that fine ſhining red colour uſed to illuminate the capital letters in manuſcripts, and more generally known by the name of *encauſtum ſacrum*, from its being uſed in ornamenting the manuſcript bibles, and its reſembling the fine red glow of the enamel of that colour.

COCCUS, in *Entomology*, a genus of the hemipterous order. The inſects of this tribe have the ſnout ſeated in the breaſt, the antennæ filiform, and the poſterior part of the abdomen furniſhed with briſtles; the male has two erect wings, and is deſtitute of poiſers, and the female is apterous, or without wings.

The cocci are a prolific race, and, like the aphides and the chermes, are the peſt of plants. They are remarkably diſcriminate in their choice of food, almoſt every ſpecies being peculiar to ſome particular plant, and this ſo conſtantly, that the far greater number of the cocci bear the name of the individual vegetable on which they reſpectively ſubſiſt. The diſſimilarity prevailing between the two ſexes is very ſtriking, not only in their form, but manners of life. The male is furniſhed with wings, and is naturally very active; the female is without wings, and has ſcarcely the appearance of animation. The females fix themſelves to the branches, leaves, and ſometimes roots of plants, where they remain immoveable, and are viſited by the males; in this ſtate of apparent torpor, they produce their young, and periſh. As the cocci live on the juices of plants, which they obtain by perforating the cortex, or cuticle, with their proboſcis, they are very injurious to plants, more particularly the tender exotic kinds raiſed in ſtoves and green-houſes. The females, when affixed to plants, oftentimes loſe the very form and appearance of inſects; their bodies ſwell, their ſkin ſtretches, and becomes ſmooth, and the ſegments, or annulations of the abdomen, entirely diſappear. In this ſtate they ſo much reſemble certain kinds of excreſcences or galls found on the leaves and branches of plants, as to be in general miſtaken for ſuch. When the inſect aſſumes this laſt appearance, its diſſolution is faſt approaching; and after its death, the abdomen ſtill ſerves as a covering, under which the eggs of the future brood are concealed and protected. Others of the coccus genus, though they adhere in the ſame manner to the leaves or branches of plants, retain the true form of the inſect till the young are produced from the egg. The females of moſt ſpecies have a quantity of fine cotton, in which the lower part of the abdomen is concealed, and which ſerves as a neſt for the eggs when depoſited by the parent inſect.

Species.

HESPERIDUM. Found generally on the orange, citron, and other plants of the ſame family, and on various evergreens reared in green-houſes. The French call it *Cochenille de l'oranger*, as it ſeems to prefer the former of thoſe trees.

The female of this ſpecies is a ſmall oval inſect, about the ſixth part of an inch in length; the back ſlightly convex, of a ſhining brown colour, with a ſmooth ſurface, and a notch in the poſterior part. It has ſix legs, and when young runs upon trees. The full-grown inſect does not envelope itſelf in a cotton-like or downy ſubſtance, like many others of the coccus tribe, but adheres, and afterwards remains attached firmly to the bark, under the form of an oval convex ſhell, or huſk, of a ſemi-tranſparent browniſh colour, with a gloſſy aſpect, as if covered with a coat of varniſh. In this ſtate the inſect dies, and ſhortly afterwards the numerous eggs concealed within the abdomen are hatched, and produce another brood. The male is a very ſmall winged inſect, and leſs frequently obſerved than the female, which latter is extremely abundant, and oftentimes proves very injurious to the plants they infeſt. The ſpecies is originally a native of the warmer regions, and has been introduced into Europe with exotic plants. An account of this inſect occurs in the Memoirs of the French Academy by De la Hire, under the title of "Deſcription d'un Inſecte, qui ſ'attache à quelques plantes etrangeres, et principalement aux orangers." t. 10. p. 10.

AONIDUM. Body purpliſh-black; crown of the head tuberculate. Fabr. Modeer Act. Gothenb. i. 30.

Inhabits various ever-green trees of Aſia; it is ſmaller than coccus heſperidum, without wings, and yellowiſh; oblong, or ſomewhat orbicular, and with antennæ nearly the length of the thorax.

CAPENSIS. Ovate, ſomewhat downy, conic-gibbous, and operculate at the tip. Modeer Act. Gothenb.

A native of the Cape of Good Hope, and infeſts the gnaphalium muricatum.

ADONIDUM. Rufous, mealy and hairy. Fabr. *Cochenille des ſerres*, Latreille. *Coccus adonidum, corpore roſeo farinaceo, alis ſetiſque niveis*, Geoffroy. *Pediculus adonidum*, Linn. Fn. Suec. *Pediculus coffeæ*, Lederm.

The moſt common inſect of the coccus tribe, and is ſuppoſed to have been originally peculiar to Senegal, from whence it was long ſince tranſported to America and Europe. The female is of an oblong-ovate form, ſlightly convex above, with the body divided into many tranſverſe ſegments, which project on the ſides, and are furniſhed with ſmall proceſſes or points; theſe proceſſes are longer on the two laſt diviſions of the body than the reſt, and form a kind of bifid tail. The whole inſect is of a pale roſe colour, and appears more or leſs covered with a fine white farinaceous ſubſtance; the legs ſhort, and ſix in number. The male is very ſmall, alſo of a roſe colour, and partially covered with a white powder, with ſemi-tranſparent milk-white wings, and four long filaments at the tail. Theſe inſects wander about the plants they infeſt, and nouriſh themſelves by ſucking the juices. When the female is full grown, and pregnant with eggs, ſhe ceaſes to feed, and remaining fixed to one ſpot, envelops herſelf in a fine white fibrous cotton-like ſubſtance, and lives but a ſhort time afterwards; the young, which hatch under the huſk or body of the parent inſect, proceeding from it in great numbers, and diſperſing in queſt of food.

QUERCUS. Found on the oak, *Quercus robur*. This is ſomewhat kidney-ſhaped, and of a brown colour.

CACTI. Found on the *cactus opuntia*, or prickly pear tree.

The coccus cacti is a native of South America, and conſidered as an article of commerce and manufactory, is of far greater importance to mankind than any other of the inſect race;—it is the true cochineal, the drug ſo well known for its valuable properties in the art of dyeing, and other uſeful purpoſes of life. The body is depreſſed, downy, and tranſverſely wrinkled; the abdomen is purpliſh, the legs ſhort and black, the antennæ ſubulate, and about one third the length of the body.

The diſcovery of this valuable inſect has contributed more efficiently to enrich the poſterity of the Spaniſh adventurers in the New World, than the wealthy mines of Peru and Mexico. The cultivation of the inſect proves a ſource of employment to the induſtry of the country; and while it improves the eſtates of the land-proprietors, conſtitutes to the benefit of the revenue a branch of commerce of the firſt importance and conſideration. This is no matter of aſtoniſhment; the properties of the cochineal of South America are ſo incomparably ſuperior to thoſe of any other dye for the

the brilliancy at leaſt, and in no ordinary degree for its durability, that its diſcovery may be conſidered as an ineſtimable advantage to the civilized world.

The coccus dye of Portugal, Sardinia, Aſia Minor, and Africa, was in the moſt general uſe in ancient times. This was univerſally imagined to be the berry, or an excreſcence of ſome vegetable, an opinion which the common appearance it aſſumes in a dried ſtate would, in a certain meaſure, juſtify. That Pliny was of this opinion, is evident from ſeveral paſſages in his writings; it was the idea of the vulgar, and he adopted it. The ſame notion, preciſely, was entertained of the Mexican cochineal; and it was only of late years, long after its valuable properties, were known in Europe, that the true origin and nature of this inſect were clearly demonſtrated.

The cochineal of Mexico is brought into Europe in the form of little grains of an irregular figure, which are roundiſh on one ſide, and wrinkled tranſverſely; the other ſomewhat flat. That in moſt eſteem is of a ſlaty grey colour, mixed with reddiſh, and covered with a fine white powder. In trade the merchant diſtinguiſhes four ſorts, the Meſtique, Campeſchane, Tetraſchale, and Sylveſtre, of which the three firſt are conſidered the beſt; thoſe are named from the places where they are produced; the laſt ſort, ſylveſtre, from being found wild without any culture. The firſt three are ſuppoſed to be of the ſame ſpecies; but we are yet ignorant whether the C. ſylveſtre, or wild cochineal, and the other are of two different ſpecies; we only know that the laſt furniſhes leſs of the tincture than the other. This M. Thierry attributes not to the inferiority of the grain, but to the cottony matter with which it is covered, this augmenting its weight and abſorbing part of the colour. The proceſs employed by the dyers for extracting the colour is ſufficiently known, neither is it ſcarcely requiſite to add that carmine, the fineſt and moſt beautiful crimſon we poſſeſs, is obtained from the cochineal See Cochineal.

The female of the cochineal inſect, in its full-grown or torpid ſtate of pregnancy, ſwells to ſuch a ſize in proportion to that of its infant ſtate, that the legs, antennæ, and proboſcis, are ſcarcely to be diſcovered, except with a good eye, or the aſſiſtance of the microſcope. It is the female only that is valuable for its dye. The male is a ſmall, and rather ſlender, two-winged fly, about the ſize of a flea, or ſtill ſmaller, with jointed antennæ, and large white wings in proportion to the body, which is of a red colour, with two long filaments proceeding from the tail. It is an active and lively animal, and is diſperſed in ſmall numbers among the females, in the proportion, according to Mr. Ellis, in the Philoſophical Tranſactions, of one male to a hundred, or a hundred and fifty, or two hundred females: ſome writers ſay even three hundred.

The plants upon which theſe inſects are raiſed by the cultivators of cochineal is the nopal, or nopalleca of the Indians, called by ſome the Indian fig-tree, and by botaniſts the *cactus opuntia*, or prickly pear-tree. The culture of this plant for the purpoſe conſiſts merely in lopping the rotten or decayed branches, and removing other plants and weeds away that might injure them. Thoſe they plant in an argillaceous earth intermixed with gravel and ſtones. The Indians of the provinces of Guaxaca and Oxaca, who attend particularly to the culture of the nopals, plant them near their habitations, and call them nopaleries.

The juice of the plant on which theſe inſects breed is their ſole ſubſiſtence. About the 15th of October, which, in Mexico, is the commencement of the fine ſeaſon, they diſtribute the cochineals upon the nopals. This operation conſiſts merely in placing the females, while they are yet young and active, in a number of ſmall neſts among the leaves, from whence they wander about over various parts of the plant, in ſearch of the particular branches to which they afterwards attach themſelves, and are viſited by the males.

The breeding of the cochineal is attended with precarious circumſtances; the cochineal is expoſed to a variety of dangers from the violence of the winds, the rains, fogs, froſts, and other cauſes, and alſo from the depredations of birds, who are very fond of theſe inſects.

When the inſects are at their full growth they are gathered and put into pots of earthen-ware, but much attention is requiſite to prevent them from getting out, as in that caſe great numbers of them would be loſt; though there is no danger of this when they are at liberty on the nopal leaves, theſe being their natural reſort, and where they enjoy abundance of delicious food; for though they often remove from one leaf to another, they never quit the plant; nor is it uncommon to ſee the leaves entirely covered with them, eſpecially when they are arrived at maturity. When they are confined ſome time in theſe pots they are killed, and put into bags.

The Indians have three different methods of killing theſe inſects; one by immerſing them in hot water, another by fire, and the third by expoſing them to the burning rays of the ſun; and it is owing to theſe different proceſſes, that the cochineals are ſometimes of a deep, and at others, of a bright red. Thoſe who uſe hot water are very careful to give it the requiſite heat, and that the quantity of water be proportioned to the number of inſects. The method of killing the creatures by fire is to put them on ſhovels, into an oven moderately heated for the purpoſe, the fine quality of the cochineal depending on its not being over dried at the time of killing the inſects. Some alſo are killed by the fumes of heated vinegar, and others by ſmoke. Thoſe killed and dried in the ſun ſeem, however, to have the preference. When the female inſect has diſcharged all its eggs it becomes a mere huſk and dies, ſo that the greateſt care is taken to kill the inſects before that time, to prevent the young from eſcaping, and thus diſappointing the hopes of the proprietor.

As this inſect attains to maturity, performs the ordinary functions of life, depoſits eggs, and dies within the ſhort ſpace of two months, according to M. Thierry, there are no leſs than ſix ſucceſſive generations of this inſect in the ſpace of a year. After being excluded from the egg, both the male and female remain ten days in the larva form, and five under that of the nymph or pupa, and are then become perfect inſects. Some writers, however, ſay, that there are only three broods of the cochineal annually, the firſt of which appears about the middle of December, and the laſt in May. It appears pretty certain that the female, after coupling, ſurvives for about a month, and that the males die immediately. Beſides the depredations committed amongſt theſe inſects by birds, the larvæ of the ſmall ſpecies of lady-bird, called by Fabricius *coccinella cacti*, is highly injurious to them, deſtroying the females while in a ſtate of torpidity with perfect impunity.

The principal countries where the cochineal inſects are bred, are Oaxaca, Tlaſcala, Chulula, Nueva Galicia, and Chiapa, in the kingdom of New Spain; and Honduras, Loja, and Tucuman in Peru: but it is ſaid to be princip in Guaxaca and Oaxaca that they are gathered in large quantities, and form a branch of commerce, the cultivation of them being there the chief employment of the natives.

Notwithſtanding ſo much has been already written on this ſubject, we are perſuaded no ſmall degree of uncer-

 tainty

tainty prevails with regard to the true hiſtory of this inſect, and time alone can develope it; we are even yet ignorant, as before obſerved, whether the kind found wild in South America is of the ſame ſpecies with that cultivated for the purpoſes of commerce; we are yet to be informed whether our own colonial poſſeſſions may not produce the ſame kind of inſects, or inſects capable of ſupplying us with the ſame kind of dye; and even whether the ſpecies of cocci indigenous, or naturalized in our own country, may not be rendered of conſiderable utility in the ſame point of view. It appears, ſtill further, from what we have ſeen, that the Eaſt Indies affords one, two, or, perhaps, more ſpecies of the cochineal tribe, which, with due attention and culture, might prove equally valuable with that of Mexico, and which, conſidering the vaſt extent of our poſſeſſions in India, might one day become the ſource of unexpected wealth. Latreille, with a degree of patriotiſm that does infinite credit to his memory, invites the particular attention of his countrymen to the ſubject; he recommends them earneſtly to attend to the indigenous products of France, ſatisfied as he is that the French need no longer remain tributary to Spain for this branch of commerce. And he addreſſes himſelf in particular to the inhabitants of the Eaſt Indies, to ſeek after, and inveſtigate another ſort of cochineal peculiar to thoſe countries, which is infinitely ſuperior in ſize to that of Mexico, as he judges by a ſpecimen brought by Maſſé, a zealous naturaliſt, to the Muſeum of Natural Hiſtory. "Le gouvernement (ſays Latreille) a le plus grand intérêt á favoriſer ces tentatives. Il me paroit aſſez démontré que nous pouvons ceſſer d'ètre tributaires d'l'Eſpagne pour cette branche du commerce. La cochenille ſylveſtre ſe perpétue dans les ſerres du Jardin des Plantes de Paris; pourquoi ne porteroit-on pas ſes regards ſur ce genre de culture, auquel d'heureuſes circonſtances ſemblent nous inviter? J'engagerois encore les naturaliſtes, ou hommes éclairés, qui habitent les Indes orientales, à ètudier une autre ſorte de cochenille qui eſt infiniment ſupérieure pour la grandeur à celle de Mexique. J'en juge par un individu que Maſſé, zélé naturaliſte, a envoyé au Muſéum d'Hiſtoire Naturelle."

It is but juſtice to ſome enlightened individuals of our own country to ſtate that the cocci of the Eaſt Indies, which produce the cochineal tincture, have not been entirely diſregarded. A ſeries of no leſs than fourteen letters on the ſubject of cochineal inſects diſcovered at Madras by Dr. Anderſon, and addreſſed to ſir Joſeph Banks, were printed and publiſhed at Madras in the year 1788, and two others in concluſion of this ſubject in 1789 and 1790; and alſo an account of the importation of American cochineal inſects into Hindooſtan. An intereſting paper on the lacſha, or lac inſect of that country, (coccus lacca), occurs alſo in the Tranſactions of the Bengal Society, vol. ii. p. 361, and in the Philoſophical Tranſactions, vol. 81.

Polonicus. On the roots of ſcleranthus perennis. Linn. Faun. Suec. *Chermes radicum purpureus*, Geoffr. *Coccus tinctorius radicum*, Breynnius Act. Phyſ. Med. p. i. p. 504. *Graine d'eſcarlate de pologne*, Latreille.

The body of this ſpecies is of an oblong ovate form, and of a purple or cheſnut colour. It inhabits Poland.

This is denominated the cochineal of the north, is found only in cold climates, and ſeems in a great meaſure peculiar to Poland, though not entirely confined to that country. It was one of the principal kinds of ſcarlet dyes in uſe before the diſcovery of South America; but as it is an article collected with difficulty, and is ſufficiently verified by experience to be in every reſpect inferior, as a dye, to the coccus cacti, or Mexican cochineal, its cultivation is leſs aſſiduouſly regarded than formerly.

Theſe inſects are affixed chiefly to the roots of plants, the principal of which is the ſcleranthus perennis; they occur alſo on the pimpernel, the pellitory, mouſe-ear, and ſome others, that grow in ſandy ſituations. Towards the end of June theſe cocci are in a fit ſtate for being gathered; they are then nearly of a ſpherical form, and of a fine violet colour. Some of them are not larger than poppy ſeeds, and others the ſize of a pepper corn, and each of them is lodged in a ſort of cup like that of an acorn, and in which more than half the body is contained. The outſide of the covering is rough and of a blackiſh brown, the inſide ſmooth, poliſhed, and ſhining. On ſome plants they find only one or two of theſe, and on others more than forty. Theſe are the females; the males are ſmaller, and have wings. About the end of June theſe inſects are quite full of purple juice, and it is at that ſeaſon they are gathered. Thoſe who gather them have a hollow ſpade with a ſhort handle; then taking hold of the plant with one hand, they raiſe it out of the ground with the tool held in the other; after which they very quickly and dexterouſly detach the inſects and replace the plant in the ground, where it again takes root. The coccus is then ſeparated from the earth by means of a ſieve; and ſprinkled with very cold water or vinegar. And, laſtly, they are killed by expoſure to the ſun, or keeping them for ſome time in a warm place; but this muſt be done with caution, as too haſty drying would ſpoil the colour. Sometimes they ſeparate the inſects from the veſicles with their fingers, and form them into balls, and by this operation increaſe the value of the article. The Turks and Armenians buy this cochineal for dyeing not only their wool and ſilk, but the tails and manes of their horſes. The women of Turkey alſo employ an infuſion of this drug in the juice of the citron or grape to ſtain the tips of their fingers, and feet, of a beautiful carnation colour. The Levantines, after the manner of the Dutch, ſometimes intermix the Poliſh cochineal in equal portion with the cochineal of Mexico, and extract from it the dye with which they ſtain their ſcarlet cloths, by means of citron-juice, or a ſolution of alum. In the preparation of colours for the artiſt, the Poliſh cochineal is of little ſervice. M. Macquer, who tried many experiments on it, could never produce with it any other than lilac, fleſh colour, or crimſon; and he found it far more expenſive than the Mexican cochineal, becauſe, although it bears an inferior price, it does not yield more than one-fifth part of the colour in proportion.

Fragariæ. On the fragaria and potentilla. *Coccus fragariæ veſcae*, S. G. Gmelin It. i. p. 205. *Coccus potentillæ*, Mayer.

A ſpecies indigenous to ſome parts of northern Europe, Pruſſia, and Siberia. This kind is diſtinguiſhed by having the ſnout black, the thorax marked with three ridges, and the tail ſurrounded by blackiſh hairs. The Ruſſians extract a ſcarlet dye from this inſect.

Hypericornis. On the hypericum perforatum. Pallas. Inhabits Ruſſia.

Ilicis. On the quercus coccifera. Fabr. Modeer Act. Gothenb. Geoffr. Mat. Med. ii. p. 782.

This is the kermes of the *Materia Medica*, and when immerſed in vinegar and dried, produces a colouring matter of a ſimilar nature and tint, but in an inferior quantity, to that of the coccus cacti. Theſe inſects are found adhering to the ſhoots of the quercus coccifera, under the form of ſmooth, reddiſh brown, or blackiſh grains, about the ſize of peas, and covered with a white down. According to M. Hellot, of the French Academy, they are found in the woods of Vauvert, Vendeman, and Narbonne; but more abundantly in Spain towards Alicant and Valencia, and in Murcia,

Murcia, Jaen, Cordova, Seville, Eftremadura, La Mancha, and Serranias de Cuenca. The infect occurs alfo in Greece, and the iflands of the Archipelago.

Before the difcovery of America, the coccus ilicis, or kermes, as it was then termed, was the moft valuable for dyeing fcarlet. Its utility was known to the ancients, but neither the ancients nor the moderns, till of late years, feem to have underftood its origin and nature. Pliny fpeaks of it as the berry of a plant; others, after him, confidered it in the fame light, or as an excrefcence formed by the puncture of a particular kind of fly, fimilar to the gall-nuts on the oak, and other plants. Tournefort was of this opinion. Marfigli, and Dr. Nifole, a phyfician at Montpellier, made experiments and obfervations, with a view to further difcoveries, but did not perfectly fucceed. Two other phyficians at Aix in Provence, Dr. Emeric and Dr. Garidel, applied themfelves about the fame time, and with more fuccefs, having finally difcovered that the kermes is, in reality, nothing elfe than an infect, affuming the appearance of a berry in the procefs of drying.

It is related in Dillon's "Travels through Spain," that in Xixona and Terra de Rellen, there is a diftrict called De la Grana, where the people of Valencia firft began to gather it, and their example was followed all over Spain. In fome years, this article has produced 30,000 dollars to the inhabitants of Xixona.

The culture of the kermes is ftill an object of confideration, though infinitely lefs fo than formerly. The people of Hinojos, Bonares, Villalba, and other parts of the kingdom of Seville, dry it on mats in the fun, ftirring it about, and feparating the red duft, which is the fineft part; this they mix with vinegar, and denominate "paftel." In other parts, the infects are gathered from the trees as carefully as poffible, without lopping the branches of the trees to which they adhere, and are fteeped in vinegar, in order to kill the parent, to prevent the exclufion of the young in drying. The kermes are then fpread or thrown on linen, and as long as they retain any moifture, are turned twice or thrice a day, till they are thoroughly dried, when they are put up for fale. The kermes of Spain is faid to be preferred on the coaft of Barbary, on account of its goodnefs. The people of Tunis mix it with that of Tetuan for dyeing fcarlet caps, fo much in ufe in the Levant. The Tunifians, according to the fame accounts, export every year above 150,000 dozen of thofe caps, which yield to the dey a revenue of 150,000 dollars.

The woollen cloths dyed with this fpecies of coccus, are of a deep red colour, much inferior in brilliancy to the fcarlet cloths dyed with the true, or Mexican cochineal, but of a more durable nature, and lefs liable to ftain. M. Hellot, to whom the world is indebted for feveral ufeful obfervations on this fubject, obferves, that the figured cloths to be feen in the old tapeftries of Bruffels, and the other manufactures of Flanders, which have fcarcely loft any thing of their livelinefs by ftanding for two hundred years, were all dyed with the kermes.

Ficus. On the ficus religiofa and indica. Fabr. *Coccus lacca kerr*, Phil. Tranf. 1781.

This is the infect which produces the gum lac, and is a native of the Eaft Indies. It is of an oval compreffed form, inferior in fize to the head of a moderately large pin; the back is carinated, the abdomen flat, the antennæ half the length of the body, and ramofe, or fending forth two or three long delicate hairs; and the tail furnifhed with two briftles.

The natural hiftory and transformations of this infect have not, hitherto, been attended to by any accurate and well-informed obferver, upon whom we may implicitly rely. The following general remarks feem more entitled to attention. Thefe infects are faid to inhabit, befides the trees abovementioned, the *plafo* of the Hortus Malabaricus, and *rhamnus jujuba* of Linnæus. They commonly fix themfelves fo clofe together, and in fuch numbers, that fcarcely one in fix can have room to complete her cell; the others die, and are eat up by various infects. The extreme branches appear as if they were covered with a red duft, and their fap is fo much exhaufted, that they wither, and produce no fruit, the leaves drop off, or become of a dirty black colour. Thefe infects are tranfplanted by birds; for if they perch only upon thefe branches, they muft carry off a number of the infects upon their feet to the next tree they reft upon. It is worth obferving, that thefe fig-trees, when wounded, drop a milky juice, which inftantly coagulates into a vifcid ropy fubftance, which, hardened in the open air, is fimilar to the cell of the coccus lacca. The natives boil this milk with oils into a birdlime, which will catch peacocks, or the largeft birds. A red medicinal gum is procured by incifion from the plafo-tree, fo fimilar to the gum lacca, that it may readily be miftaken for the fame fubftance. And hence it is fuppofed, thefe infects have little trouble in animalizing the fap of thefe trees in the formation of their cells. The gum lacca is rarely feen upon the rhamnus jujuba, and it is inferior to what is found upon the uncultivated mountains on both fides of the Ganges, where nature has produced it in fuch abundance, that were the confumption ten times greater, the markets might be fupplied. The only trouble in procuring the lac, is in breaking down the branches, and carrying them to market. The price in Dacca, a few years ago, was about 12*s*. the hundred weight, though brought thither from the diftant country of Affam. The beft lac is of a deep red colour. This infect and its cells have gone under the various names of gum lacca, lack, and loc tree; in commerce, they diftinguifh four kinds of this fort of gum.

Caricæ. On the ficus carica. *La cochenille du figuier commun*, Olivier. The body is ferruginous, with the margin elevated and pale. Its general figure is oval, and convex. This defcription applies only to the female, as the male is yet unknown.

This kind is found in the fouth of Europe, and throughout the Levant, where they commit vaft depredations on the fig trees, to which they are peculiar. Thefe infects are fo numerous, that it is impoffible to deftroy them, and in fome feafons in particular, they appear in fuch immenfe fwarms, as to defpoil the trees of their foliage, and rob them of their moifture, till they occafion the fruit to drop off before it can ripen. Some cultivators of the fig fprinkle their trees with a mixture of vinegar and the dregs of oil, and which, in a partial degree, may prove efficacious in deftroying them.

Uvæ Ursi. On the roots of arbutus uva urfi. Fabr. The body of this infect is a chefnut colour, and produces a tincture. Modeer Act. Gothenb.

Characias. *Cochenille du characias.*

This curious infect was firft defcribed by Bofc in the "Journal de Phyfique," February, 1784, under the name of *Dorthefia characias*, in memory of his friend Dorthes de Montpellier, who had previoufly obferved it. The male is about a line and a half in length exclufive of the wings, which are very large, femi-tranfparent, and of a leaden-grey colour. The antennæ are fetaceous, and much longer than the body, and the extremity and upper part of the abdomen are tufted with white hairs or filets, which extend beyond the end of the wings. The female is larger than the male, meafuring

meafuring two or three lines in length, the antennæ are fhort, filiform, and of a reddifh brown, and entirely covered with a whitifh matter, which forms appendages or tufts on the fides and on the back. The abdomen terminates in a folid friable mafs of long filets, upon removing which the body appears reddifh; with nine tranfverfe ftriæ. The trunk is fhort and fituated in the fpace between the anterior legs. The legs are of a reddifh brown. Preparatory to the fe-male beginning to lay her eggs, which fhe does at the commencement of the fpring feafon, fhe forms a little elongated receptacle fomewhat in form of a fack, and fills it with a white cotton-like fubftance, in which the eggs are depofited. Thefe infects prefer the *euphorbia characias*, and *euphorbia pilofella*, two plants on which they thrive, and are rarely found on any other. The young fhed their fkins feveral times before they acquire their full fize. The wings of the male appear, when they have caft their fkins the third time, in the month of September; the latter are rare, compared with the females, not more than one or two males being found to two or three hundred females. Their amours and habits refemble thofe of the other cocci. A circumftance apparently new in the hiftory of the cocci was obferved by Dorothes relative to this infect. He found that the females furvive after laying their eggs; in the winter they conceal themfelves under ftones, or among the bark and moffes, and re-appear in fpring, when the young are hatched, and the parent lives at leaft a month afterwards. It is faid that the larva of a particular kind of coccinella infinuates itfelf in the receptacle of eggs, and eats them without attacking the parent. Olivier appears to have found the fame fpecies of coccus on the bramble in the neighbourhood of Paris.

The coccus characias emits from the pofterior part globules of a vifcous matter, refembling the faccharine moifture difcharged by the aphides. Some attempts have been made to difcover whether thefe infects might be rendered of any utility to the dyer, but without fuccefs; an infufion of them in boiling water produces only a weak tincture of a pale yellow colour.

Cataphractus. Milk-white; eyes, antennæ, roftrum, and legs ferruginous.

This curious infect was defcribed by Dr. Shaw, in the fifth volume of the "Naturalifts' Mifcellany," from a fpecimen communicated by Mr. Dickfon, gardener to the Britifh Mufeum. Dr. Shaw confiders it as a fpecies of coccus, an opinion that feems to admit of fome doubt, but as the infect is unknown to us, except from the defcription, we fhall retain it in this genus, and only repeat the account given of it by that writer in his own words.

"The natural fize of the infect (of which the female alone appears to be at prefent known), is that of the coccinella tigrina, or fmall yellow-fpotted lady-bird, and at firft view has an appearance fo little allied to the generality of the cocci, as to make it doubtful whether it really belongs to that tribe of infects. The whole animal (except the eyes, legs, antennæ, and roftrum,) being coated, in the moft curious manner, in a complete fuit of milk-white armour, as if cafed with ivory. The divifions or annuli of the back are eight in number, of which the three fuperior ones are each furnifhed with a fmall fcutellum or appendicular piece, which is wanting in the other. The fides are furrounded by projecting laminæ, fomewhat in the manner of tortoifes or millepedes; the lower furface is compofed of angular pieces, difpofed nearly as in the former of the abovementioned animals; the eyes which are fituated juft below or on the underfide of the antennæ, are bright, and fomewhat elevated, not unlike thofe of a lobfter; the colour of the projecting parts, *viz.* the legs, eyes, antennæ, and roftrum, is a fine bright ferruginous or reddifh brown." The eggs were fmall in proportion to the animal and of a brown colour. This infect is found among fphagnum and other moffes in boggy and turfy ground, and is moft frequent in Scotland, Ireland, and the north of England, particularly in fome parts of Cumberland.

Oleæ. Feeds on the olive, myrtle, and phyllyrea. Oliv.

Olivier defcribes this fpecies under the name of *Coccus oleæ*, and *Cochenille de l'Olivier*. The female is oval, and of a red-brown colour, paler or deeper in different individuals, and with the nerves, raifed and irregular. The male is unknown. This is found in the fouthern parts of France and in Italy: it chiefly infefts the olive, and, though common on the leaves of that plant, is obferved never to touch the fruit. The young, foon after being hatched, difperfe, and refort to the under fide of the leaves and buds. They multiply prodigioufly faft, and are, of courfe, injurious to the olive which they particularly prefer.

Rusci. Shell furrounded by eight fmaller pieces. Modeer Act. Gothenb.

Inhabits Italy; on the Myrtus and Rufcus. The fhell is truncated, octagonal, and perforated, and has the fmaller lateral pieces granulated in the middle.

Myricæ. Feeds on the *myrica quercifolia*, Fabr. Modeer Act. Gothenb.

A native of the Cape of Good Hope. This is the fize of a fmall pea, and of a femi-oval form, and pale flefh colour: the crown is obtufely pointed, and furnifhed with a very fmall pore, and another above the thicker cartilaginous membrane.

Capreæ. Feeds on the willow. Modeer Act. Gothenb. *Coccus fubrotundus fufcus, linea dorfali nigra*, Degeer.

Size of a fmall pea, and of an ovate form, with the anterior part obtufe and bifid; the colour teftaceous or fufcous, with a gloffy furface, and marked down the middle with a line of black. An European fpecies.

Phalaridis. On the roots of graffes, particularly the *phalaris canarienfis*, or canary grafs.

This kind is defcribed by Linnæus in his "Fauna Suecica," under the name of *Coccus phalaridis*. Geoffroy calls it *Coccus graminis, corpore rofeo*. The female forms little nefts along the ftalks, and at the roots of grafs, which are compofed of a white cotton-like fubftance, in which fhe depofits her eggs. The body of the female is pale-red, or whitifh, and mealy; the male is of the fame colour, with two wings, and four threads at the extremity of the tail, two of which are longer than the reft.

Cratægi. Feeds on the hawthorn, *Cratægus oxyacantha*, Modeer Act. Gothenb.

Inhabits Europe; is of an oblong form, and chefnut colour.

Serratulæ. Feeds on the faw-wort, *ferratula arvenfis*, Fabr. Found in England.

Zosteræ. Feeds on the *zoftera marina*. Fabr.

This is about the fize of a pea; the fhields are brown, and paler at the edges. Found chiefly on the *zoftera marina* in the Baltic.

Vitis. On the branches of *vitis vinifera*. Fabr. *Chermes vitis oblongus*, Geoffroy.

The body of this fpecies is oblong, and of a cinnamon colour.

Liriodendri. Feeds on the *liriodendrum tulipifera*. Hamburgh Mag.

Farinosus. Ovate, downy, pale fufcous, powdered with white. Modeer Act. Gothenb.

Infefts the *betulus alnus*. The body of this fpecies is depreffed.

Clematidis. Feeds on plants of the *clematis genus*. Geoffr.

Persicae. Feeds on the *amygdalus persica*. Modeer Act. Gothenb.

The body of this species is glossy, and either of a reddish colour, tawny, or black.

Abietis. On the *pinus abies*. Modeer. *Le kermès du sapin* of Geoffroy.

This is of a round and spherical form, and of a deep maroon colour: it is found on pines near the bifurcations of the branches.

Fuscus. On the oak, *quercus robur*. Modeer. Body brown and mealy, and of a rotundate form.

Variegatus. Round, variegated with white, yellowish, and black.

The general colour is a yellowish-white, marked with three black transverse rays, and the intermediate spaces dotted with black.

Lanatus. Oblong, silky white; on the *quercus robur*. Geoffroy.

This is of a brown colour, and assumes a white appearance from the silky down with which the body is covered.

Mespili. Body silky-white; on the *mespilus*. Called by Geoffroy *Le kermès cotonneux du néflier*.

Concholiformis. Body linear, and fuscous; on the elm. Modeer.

Aceris. Body ovate; on the maple. Modeer.

Laniger. Brown, silky-white; on the *ulmus campestris*. Reaum.

Diosmatis. On the *diosma crenata* and *pulchella*. Modeer.

Alni. In the divisions of the branches of *betula alni*. Modeer. The body is of an oblong-ovate form, and reddish.

Uva. Fuscous, inclining to yellowish, and sphærico-gibbous. Modeer. Inhabits Sweden, and is found under stones.

Spurius. Ovate, with a few hairs, chesnut; beneath pale yellow. Modeer. Found on the ulmus, or elm.

Coccus *Maldivia*, the Maldivia nut, in the *Materia Medica*, the name of the fruit of the *palma Maldiviensis* of Johnston, an oval-figured fruit, of a sweet taste, and famous for its virtues in nervous disorders.

COCCYGÆUS Musculus, in *Anatomy*, is a thin and flat muscle, of a triangular figure, arising by its apex from the point of the spinous process of the sacrum, and inserted by its basis into the inferior lateral part of the sacrum, and into the side of the os coccygis. It is strongly connected to the lesser sacro-ischiatic, or spinoso-sacral ligament. It will restore the os coccygis, when that bone has been carried backwards; and it may bend this bone forwards. This muscle is the *levator coccygis* of Morgagni; *triangularis coccygis* of Santorini; and *sacro-coccygeus* of Winslow.

COCCYGIS *curvatora*, is a thin and slender muscle, derived from the inferior lateral portion of the inner surface of the sacrum, and from the upper part of the os coccygis; it is fixed into the lower bones of the coccyx. It is often, mostly or entirely, tendinous. It will bend the coccyx forwards.

Coccygis *ossis musculi*. These are small, thin, radiated muscles, lying on the inner, or concave side of the os sacrum, and neighbouring parts of the pelvis. They are four in number, two on each side, one placed more forward, the other more backward; for which reason the first may be termed *coccygæus anterior*, sive *ischio coccygæus*, and the other *coccygæus posterior*, sive *sacro coccygæus*.

COCCYGIUS, in *Ancient Geography*, a hill of the Peloponnesus, in the Argolide territory. The way from Troezené to Halicé, passed by the foot of this hill, on which was a temple, dedicated to Jupiter; and an old temple at the bottom of the hill is said to have been consecrated to Apollo. This hill was near the river Inachus, according to Plutarch and Pausanias, the latter of whom calls it *Coccyx*.

COCCYGRIA, in *Botany*, Bauh. Pin. See Rhus *cotinus*.

COCCYNUM Promontorium, in *Geography*, a promontory of Italy, in Magna Græcia, opposite to Sicily. Appian.

COCCYX, or Ossa Coccygis, in *Anatomy*, three or four small portions of bone, connected with each other, and joined to the inferior extremity of the sacrum. See Skeleton.

Coccyx, in *Ichthyology*, a name given by Aristotle, and other old Greek writers, to the fish called *cuculus*, and *lyra*, by other authors. It is a species of the *trigla*, distinguished by Artedi by the name of the *trigla*, all over red, with a bifid snout, and the coverings of the gills striated.

COCETUM, among the *Ancients*, a kind of drink made of honey and poppies.

COCHA, in *Ancient Geography*, a town of Arabia Deserta. Ptolemy.

COCHABAMBA, in *Geography*, a province and jurisdiction of Peru, the new vice-royalty of La Plata, or Buenos Ayres, situated in a fertile valley between mountains, and watered by a river of the same name. The adjacent provinces are Sicasica to the N.W.; La Paz and Cruso to the W. and S.W.; Chayanta to the S.; and to the E. Plata and Santa Cruz de la Sierra, in S. lat. about 18°, and W. long. about 67°. The capital town is Oropesa, and it was formerly denominated the granary of Peru. It has one gold mine.

COCHE, in *Ancient Geography*, a village of Babylonia, near Seleucia, to the S. E.

Coche, in *Geography*, a small island in the Caribbean sea, between the island of Margarita and the continent of South America. N. lat. 10° 57′. W. long. 63° 10′.

COCHECO, a north-west branch of Piscataqua river, in the state of New-Hampshire, in America. It rises in the Blue hills in Strafford county, and its mouth is 5 miles above Hilton's Point.

COCHER, a river of Germany, which runs into the Neckar near Wimpfen, in the circle of Swabia.

COCHEREL, a town of France, in the department of the Eure, famous for a victory gained by Guesclin over the king of Navarre in 1364; 7 miles E. of Evreux.

COCHHEIM, or Kocheim, a town of Germany, in the circle of the Lower Rhine, and electorate of Treves, now belonging to the French, and chief place of a canton in the department of the Rhine and Moselle, and district of Coblentz, seated on the Moselle, formerly imperial, but engaged to the electorate of Treves in 1240 by the emperor Adolphus de Nassau; 30 miles N.E. of Treves, and 46 N.E. of Luxemburg. The place contains 1527, and canton 5647 inhabitants. The territory includes 18 communes.

COCHIA, in the *Materia Medica*, the name of officinal pills, which are distinguished into the greater and lesser: the former is a composition of hiera picra, troches of Alhandal turpeth, diagrydium, and syrup of buckthorn, taken from Rhases, but seldom used in the present practice. The latter is compounded of equal quantities of bright aloes, the purest scammony, and the pulp of colocynth, made into a mass with syrup of buckthorn; two drams of the distilled oil of cloves are added to an ounce of each of the former ingredients. These pills are prescribed to discuss viscidities, watry humours, and flatulencies.

COCHICAT, abridged from the Mexican name *Cochitenacatl*,

nacatl, in *Ornithology*, the *Psittacus torquatus* of Gmelin, the *Ramphastos torquatus* of Latham. Ind., the *Tucana Mexicana torquata* of Brisson, and the *Coloured Toucan* of Lath. Syn.; has the following specific character: Above it is black, below whitish, its belly green, its hind part red, and its collar of the same colour. It frequents the sea-shore, and lives on fish.

COCHILE, or Coscile, in *Geography*, a river of Naples, which runs into the gulf of Tarento, between Cassano and Rossano, in the province of Calabria Citra.

COCHIN, a sea-port town of Hindoostan, on the coast of Malabar, formerly occupied by the Portuguese, afterwards the chief settlement of the Dutch, but now in possession of the English; it is situated in a country N. of Travancore, to which it gives name, and which has been chiefly resorted to for pepper. Cochin stands at the N.W. of an island, which is about 18 Dutch miles in length, and two in breadth; to the south the island is formed by the mouth of the river of Cali Coylang, and to the N. by that which runs from Cranganore, and separates it from the island of Baypin. The form of the city is nearly semicircular, and it is about $1\frac{1}{2}$ mile in circumference. Cochin, besides the bastions, cavalier and wall by which it is fortified, has three gates, to the W. to the E. and to the N. Its principal buildings are the church and the government-house. Its streets are generally wide, but there are few handsome houses. The whole country in the vicinity of Cochin abounds with lakes, which are the repositories of the waters that spring from the west side of the Gauts, and is very flat, marshy, and insalubrious. At Cochin there were, at the beginning of the last century, about 4000 Jews, descendants, probably, of those who fled through Persia to the coast of Malabar, from the persecution of Titus. They had a synagogue, in which were carefully kept their records, engraven on copper-plates; so that they could show their history from Nebuchadnezzar to the present time. Wolfius, cited by Kennicott (State of the printed Heb. Text, vol. ii. 532.), is of opinion, that the Hebrew MSS. of Malabar claim a considerable degree of confidence. N. lat. 9° 58′. E. long. 76° 2′.

Cochin, Nicholas, in *Biography*, an engraver of considerable merit; he was born at Troyes, in Champagne, but settled in Paris, where he engraved a great number of plates, not unfrequently in the style of Callot, whose disciple he probably was; and, like that great master, he most excelled in small figures. Many of his prints are from his own compositions. Amongst his other works are, part of the plates for the entry of Lewis XIV., with his queen, into Paris. This work, consisting of 22 prints, was published 1622. Part of the plates for a large volume in folio, of battles, plans, views of towns, &c. relative to the conquests of the French army under the same monarch, published 1645. Various sets of small prints from the Old and New Testament, &c. described by Strutt and Heinecken.

Cochin, Noel, or Natales R., an engraver, born at Troyes, and in all probability of the same family with the preceding artist. He worked at Paris about 1670, and afterwards went to Italy, and died, as it is supposed, at Venice. We have by him many bold, but coarse, etchings from the works of Titian, Tintorett, the Caracches, and other Italian artists, and, among others, several of the plates for a work, entitled, "Tabellæ, selectæ ac explicatæ à Carola Catherina Patina, Parisina Academica Batavii, 1691." This work was also published at Venice in the same year, with an Italian translation of the descriptions. The prints, however, owe their chief value to the merit of the compositions from which they are engraved. Strutt. Heinecken.

Cochin, Charles Nicholas, in his youth applied himself to painting, but afterwards quitted the palette for the graver.

He was received into the Royal Academy of Paris in 1731, and died in 1754. His numerous prints, though somewhat mannered, are executed in an agreeable and spirited style. Amongst his best works are: "The meeting of Jacob and Esau," from Le Moine; and "Jacob and Laban," its companion, from Restout; both upright plates of a middle size. He likewise engraved the two studies of Raffaele, for the "Alexander and Roxana," in the Crozat cabinet. Strutt. Heinecken.

Cochin, Charles Nicholas, son of the preceding artist, was born at Paris in 1715, and, assisted by the instructions of his father, and his mother Louise Madeleine Hortemels, became an engraver of considerable celebrity. In 1749, he travelled to Italy with the marquis de Marigny, and after his return, was, in 1752, made a member of the Royal Academy of Paris, and, in the sequel, appointed secretary and historian to that society.

In addition to these honours, he was made a knight of the order of St. Michael, and keeper of the king's drawings. Of his works, then extremely numerous, Mr. Jombent published a catalogue in 1770. He was living, according to Mr. Strutt, in 1785, when that gentleman published his dictionary. Heinecken. Strutt.

COCHIN-CHINA, in *History* and *Geography*. The extensive empire of China terminates on the south of the 22d degree of latitude; but a tongue of land continued with it extends on its western side as far as the ninth parallel of north latitude. This prolongation of 13 degrees in extent, has a ridge of high mountains, which, running from north to south, divides the Birman empire on the west, from the kingdoms of Tung-quin, or Tong-quin, Cochin-china, Tsiampa, or Siampa, and Cambodia, on the east. These names, though usually marked on our charts, are unknown to the natives, except Tung-quin. The other three, collectively, are called An-nan, and are distinguished by three great divisions. The first, contained between the southernmost point, which forms the extremity in the gulf of Siam, and which lies in about the ninth degree of latitude, as far as to the twelfth degree, is called Don-nai; the second, extending from hence to the fifteenth degree, Chang; and the third, between this and the seventeenth degree, where the kingdom of Tung-quin commences, is called Hué. On the sea-coast of all these divisions, are safe and commodious bays and harbours. The great river of Don-nai (Cambodia on the chart) is described as navigable by ships of the largest size to the distance of forty miles, where the city Sai-gong is situated, having a capacious and a commodious port, and an extensive naval arsenal. In the division of Chang, in latitude 13° 50′ N., is Chin-chen bay and harbour; the latter spacious and completely sheltered from all winds, but only accessible by large vessels at high water, on account of a bar that runs across the narrow entrance between it and the outer bay. At the head of this harbour is situated the city of Quin-nong. The principal city in the division of Hué, which bears the same name, is situated on the banks of a large river, navigable by ships of a considerable burden; but a bar of sand runs across the mouth. A little to the southward of this river is the bay of Han-sare, or, as it is usually marked in the charts, Turon, which, for the security and conveniences it affords, is equalled by few in the eastern world. It is situated in N. lat. 16° 7′.

Cochin-china, properly so called, extends from about the 20th degree of north latitude to Pulo Condore, which lies in 8° 40′. It is bounded by the kingdom of Tong-quin on the N., from which it is separated by the river Sungen, by the kingdom of Laos, and by a range of mountains, which divides

vides it from Cambodia on the W.; and by that part of the eastern ocean, called the Chinese sea, on the S. and E. The kingdom is divided into 12 provinces, lying upon the sea-coast, and succeeding each other from north to south. Its breadth bears no proportion to its length; as few of the provinces extend further than a degree from east to west, and some less than 20 miles. The whole country is intersected by rivers, which, though not large, are favourable to inland commerce. The climate is healthy, as the violent heat of the summer-months is tempered by regular breezes from the sea. The rainy seasons are September, October, and November; when the low lands are liable to be suddenly overflowed by immense torrents of water that flow from the mountains. These inundations, which happen generally once a fortnight, last three or four days. The frequent rains which are brought in December, January, and February, by cold northerly winds, distinguish this country by a winter different from any other in the East. The inundations, like the overflowings of the Nile in Egypt, contribute very much to fertilize this country; so that in many parts the land produces three crops of grain in the year. All the fruits of India are found here in the greatest perfection, with many of those of China. Asiatic Register. iii. 84.

History of Cochin-china. This country had a share in all the early revolutions of Tung-quin; it was subject originally to the Chinese government, and of course liable to the same changes which China itself experienced. In many periods of its history, Cochin-china seems to have stood high in the estimation of the parties contending for rule. When the Ming had expelled the Mogul Tartars from China, the new emperor, chief of that dynasty, sent notice to the king of Cochin-china of his accession to the throne, and caused sacrifices to be offered up in honour of the spirits of mountains, forests, and rivers. Itataha, who was then sovereign, sent his tribute to the new monarch, from whom, in return, he received magnificent presents. In 1373, this same prince made so many naval captures from the pirates who infested the seas, that he was enabled to present the emperor with seventy thousand pounds weight of precious woods.

In the next century, after a long and very bloody war, the kings of Tung-quin became absolute masters of Cochin-china, as far as cape Aurilla, in N. lat. 12° 34′. The aborigines, called Moys, retired to the mountains that separate Cochin-china from Cambodia, where they have ever since remained. They are said to be a savage race of people, very black, and in their features resembling the Caffres.

After this revolution, the Chinese historians speak but little of Cochin-china. It, however, recovered its independence, and continued to be governed, as it is at present, by its own kings. There is, notwithstanding this, but little come down to us of its history, till what is given us by Mr. Barrow, which commences in the year 1774, and of which the following is a brief outline.

In the year 1774, and in the 35th year of the reign of Caung-shung, king of Cochin-china, an insurrection broke out in the city Quin-nong, the capital of his kingdom. This rebellion was headed by three brothers, of whom the eldest, named Yin-yac, was a wealthy merchant, who carried on an extensive commerce with China and Japan: the name of the second was Long-niang, a general officer of high rank, and great command; and the third was a priest. Such a dangerous combination of wealth, of military power, and of influence over the minds of the people, was but feebly resisted on the part of the king, who had for many years surrendered, in a great degree, the reins of government into the hands of his generals, who were mostly eunuchs. Other circumstances tended to forward the views of the rebel chiefs. The imposition of a poll-tax had created general discontent among the people. They seized upon the king, whom, with as many of his family as they could get into their hands, they put to death. The city of Sai-gong was supposed to be favourable to the cause of the deposed sovereign: an army was therefore marched against it, the city was taken, and 20,000 of its inhabitants put to the sword. The usurpers left no measures untried, nor suffered any occasion to pass by, which might be the means of giving them popularity. The merchant gave sumptuous entertainments, fetes and fire-works: the general encouraged and flattered his army, and the priest prevailed on the clergy to announce to the multitude the decree of Tien, which had ordained these three worthies to be their future rulers. According to a plan laid down for the government of this extensive country, it was determined that Yin-yac should possess the two divisions of Chang and Don-nai: Long-niang that of Hué, bordering on Tung-quin; and that the youngest brother should be high priest of all Cochin-china. Thus Yin-yac placed his brother between himself and the Tung-quinese, who were regarded as a very powerful people; with these Long-niang took occasion to quarrel, but they were unable to cope with him. Their king, after the first engagement, abandoned his army, and fled to Pekin to implore the assistance of the emperor. Kien-Lung, who, from his successes in every part of Tartary, and on the great island of Formosa, had been led to believe that his troops were invincible, conceived there would be but little difficulty in driving the usurper from Tung-quin, and in restoring the lawful sovereign to his throne. For this purpose he ordered the viceroy of Canton to march immediately at the head of 100,000 men. Long-niang, apprized of the movements of this immense army, and having ascertained their line of march, sent out detachments to plunder and destroy the towns and villages, through which it must pass: the country being thus laid waste, the Chinese army, long before it had reached the frontier of Tung-quin, was so distressed by the want of provisions as to be obliged to fall back; but in their retreat they were harrassed by the enemy to such a degree, that by fatigue, famine, and sword, half the Chinese army was destroyed without a general battle being fought. The viceroy, when he was within 100 miles of Canton, offered to negociate with the usurper, but Long-niang assuming the character and tone of a conqueror declared, that having been called to the throne of Tung-quin by the will of heaven and the voice of the people, he was determined to maintain his right to the last extremity: that he had 200,000 men in Tung-quin, and as many in Cochin-china, ready to die in his cause: and that he was no longer an usurper, for he had been crowned Quang-tung, king of the united kingdoms of Tung-quin and Cochin-china. The viceroy was but ill prepared for this decided tone: yet no time must be lost in deliberation. He dispatched a courier to Pekin, giving an account of victories gained, and enemies subdued, although himself had been driven before the enemy without once daring to hazard an engagement. At the same time he spoke in high terms of commendation of his antagonist, and of his right to the crown for which he had been contending, and gave it as his opinion that Quang-tung should be invited to the court of Pekin to do the usual homage, and to receive the sanction of the emperor for holding the throne of Tung-quin; suggesting, also, that a degree of mandarinate in one of the provinces of China, conferred on the late sovereign of that country, would be an ample indemnification for the loss he had sustained in Tung-quin. The court approved the viceroy's propofal. The fugitive king of Tung-quin relinquifhed his pretenfions to a crown, and accepted the degraded title of a Chinefe Mandarin: after which an invitation was difpatched to Quang-tung to proceed to Pekin. The wary general fent an officer as his reprefentative, who was to act the part of the new king of Tung-quin and Cochin-china. He was received at the court of Pekin with all due honours, loaded with prefents, and confirmed in his title to the united kingdoms, which were to be regarded as tributary to the emperor of China. On the return of this mock king to Hué, Quang-tung knew not how to act; but perceiving that the affair could not remain a fecret, he caufed his friend and the whole fuite to be put to death, as the only means of preventing the trick which had been fuccefsfully played on the emperor of China, from being difcovered. This event happened in the year 1779. At the time of the rebellion in Cochin-china, there refided at court a French miffionary of the name of Adran, who was ftrongly attached to the royal family, and who effected the efcape of the queen and her fon. By favour of the night they fled to a confiderable diftance from the capital, and took refuge in a foreft. Here for feveral months the young king of Cochin concealed himfelf, and the remnant of his unfortunate family, in the fhady branches of a banana-tree, where they received their daily fuftenance from the hands of a Chriftian prieft, who carried them fupplies at the hazard of his life, till all farther fearch was given up. As foon as the enemy had retired, the unfortunate fugitives made the beft of their way to Sai gong, where the people flocked to the ftandard of their legitimate fovereign, whom they crowned as king of Cochin-china, under the name of his late father, Caung-fhung. At this time there were in the port of Sai-gong an armed veffel commanded by a Frenchman, feven Portuguefe merchantmen, and a confiderable number of junks and row-boats. Thefe the king purchafed for the purpofe of making an attack on the ufurper's fleet, in the harbour of Quin-nong. The monfoon was favourable for the project, but the refult was not crowned with fuccefs, and the young monarch was glad to make a hafty retreat. Though a confiderable part of Yin-yac's fleet was difabled or deftroyed, it anfwered no other purpofe than to roufe his attention towards the fouthern parts of the country. Caung-fhung had fcarcely returned to Don-nai, which he reached with difficulty, on account of the monfoon being adverfe to his return, when intelligence was received that a large army was on its march againft him. Refiftance on his part being in vain, he determined to feek for fafety in flight. Having collected the remains of his family, and a few faithful followers, he embarked in the river of Sai-gong, and after a fhort voyage, arrived fafely on a fmall uninhabited ifland in the gulf of Siam, called Pulo Wai. Here he was joined in a fhort time by about 1200 of his fubjects fit to carry arms. The ufurper having difcovered the place of his retreat was upon the point of fending out an expedition againft him, but Caung-fhung, apprized of his intention, deemed it more prudent to embark for Siam, and to throw himfelf on the protection of the king of that country. He had not been long landed before he offered his affiftance, and that of his people, to join his Siamefe majefty againft the Birmans: thefe he foon reduced to the neceffity of fuing for peace on any terms. Caung-fhung returned to the capital of Siam, where he was received with univerfal joy, and every demonftration of kindnefs, on the part of the king, who loaded him with prefents of gold, filver, and precious ftones. He did not remain long in favour, but was obliged with his adherent to feek refuge again in their folitary ifland. Here he fortified himfelf fecurely againft his enemies, and in a fhort time, learnt through his friend Adran, that the greater part of his fubjects were ftill attached to him, and diffatisfied with the ufurper. He committed his fon to the care of Adran, who embarked with his charge for Pondicherry, and from thence they failed to Paris, where they arrived in the year 1787. The young prince was prefented at court, and treated with every mark of refpect. In the courfe of a few months Adran concluded a treaty between Louis XVI. and the king of Cochin, in which the former engaged to lend Caung-fhung effectual affiftance to reftore him to his own throne. The fcheme was, however, fufpended firft by the devices of an artful woman, and afterwards completely abandoned by the French Revolution in 1789. The bifhop neverthelefs did not defpair of the caufe; he, with the young prince and fome volunteers from France, went in fearch of the king. At the mouth of the river leading to Sai-gong they learned that the monarch had remained two years, living, like the reft of his adherents, on the roots which they dug from the ground, but that he had at length raifed his ftandard in Don-nai. In the year 1790, the bifhop and his fon joined him at Sai-gong; they were followed by a fmall veffel which had been taken up to convey arms and ammunition. The greater part of the firft year was occupied in fortifying the place, in recruiting and difciplining the army, and in collecting and equipping a fleet. In the year 1791, the rebel Quang-tung died at Hué, leaving behind him a fon of about 12 years of age to fucceed in the government of Tung-quin, and the northern part of Cochin-china. Caung-fhung immediately commenced operations againft Yin-yac; the attack was fo wholly unexpected on the part of Yin-yac, that he and his court had gone thirty miles up the country to enjoy the pleafure of hunting. On fuch occafions the fovereign is not only attended by a few courtiers, but with numbers fufficient to compofe a fmall army. They are chiefly foldiers, who furround the thickets, and having fprung the game, which is ufually an elephant, or tyger, or buffalo, they diminifh the diameter of the circle, till fixing the animal on a fpot, they either kill him with their fpears or take him prifoner. The alarm of the enemy was quickly communicated to the hunting party, and the beach was prefently lined with troops: but they were of little affiftance, and the ufurper had the mortification of witneffing the deftruction of his fleet by that of Caung-fhung. In the year 1793, when the Britifh fquadron, in its way to China, came to anchor in Turon-bay, it was known that the whole of Donnai was in poffeffion of the lawful fovereign. Chang, the middle part of the country, was held by the ufurper Yin-yac; and Hué, including the country and iflands adjacent to Turon-bay, was governed by the fon of Quang-tung. At firft it was fuppofed that our fleet had come in aid of the legitimate fovereign, and under this idea, his opponents affembled a confiderable body of troops and elephants in the vicinity of Turon, and it was not till after many days had expired, that this impreffion was done away. The rebel, Yin-yac, did not long furvive the deftruction of his fleet: he died a few months after the Britifh left Turon bay of a difeafe brought on by rage and defpair at the fuccefs of the lawful king: by fome, however, his death has been imputed to poifon adminiftered by his fubjects already wearied with his government. He was fucceeded by his fon, who poffeffed all the vices without the talents of the father. Cruel, deceitful, and vindictive, he was univerfally hated. In the year 1796, Caung-fhung refolved to attack his capital

tal by land. The young usurper brought against him an army of 100,000 men; but the king completely routed it with a much inferior force, and took possession of Quinnong. On this occasion an extraordinary instance of magnanimity is related of Caung-shung. When the garrison had surrendered, the king, having been engaged in person the whole day, and worn out with fatigue, was conveyed into the citadel in a sedan-chair; but, on passing the inner gate, he was fired at by a person on the rampart: the culprit was seized and brought before the king, when it was discovered that he was a general officer, and a relation to the usurper. The king, according to the custom of the Chinese, when it is intended to mitigate the sentence of death passed on a criminal, told him, that instead of ordering his head to be struck off, he would allow him his choice of poison, a cord of silk, or a dagger. "If you are not afraid of me," said the rebel chief, "you will instantly order my release; and as I have sworn never to live under your protection, or to be obedient to your laws, if you dare comply with what I ask, I shall immediately repair to Hue, where my rank and character will procure me the command of an army, at the head of which I shall be proud to meet you." The king ordered his release, and caused him to be escorted to the northern frontier; and the following year this very man was second in command at the siege of Quin-nong where he lost his life. The son of Yin-yac was completely subdued, and the whole country, as far as Turon-bay, submitted to the arms of the lawful sovereign. The other usurper still kept possession of the kingdom of Tung-quin, against which Caung-shung was preparing a formidable armament in the year 1800, since which there have been no authentic accounts, though, according to Mr. Barrow, there are grounds for believing that he has re-conquered the whole of that country. From the year 1790, in which Caung-shung returned to Cochin-china, to 1800, he was allowed to enjoy only two years peace; these, however, were probably the most important in his hitherto troublesome reign. Under the auspices of the bishop Adran, who, in every undertaking of consequence, was to him as an oracle, he turned his attention to the improvement of his country. He established a manufactory of salt petre, opened roads of communication between important posts and considerable towns, and planted them on each side with trees for the sake of shade. He encouraged the cultivation of the areca nut and the betel pepper, the plantations of which had been destroyed by the army of the usurper. He held out rewards for the propagation of the silk worm; caused large tracts of land to be prepared for the culture of the sugar-cane; and established manufactures for the preparation of pitch, tar, and resin. He caused several thousand match-locks to be fabricated; he opened a mine of iron ore, and constructed smelting-furnaces. He distributed his land forces into regular regiments; established military schools, where officers were instructed in the doctrine of projectiles and gunnery by European masters; and Adran translated into the Chinese language a system of military tactics for the use of his army. In the course of these two years he constructed three hundred large gun-boats, five luggers, and a frigate built upon the French plan. He caused a system of naval tactics to be introduced, and had his naval officers instructed in the use of signals. An English gentleman, in the year 1800, saw a fleet of 1200 sail, under the immediate command of this prince, weigh their anchors, and drop down the river in the highest order, in three separate divisions, forming into lines of battle, and going through a variety of manœuvres by signals as they proceeded. During this interval of peace he undertook to reform the system of jurisprudence: he abolished several species of torture, and he mitigated punishments that appeared to be disproportionate to the crimes of which they were the consequence. He established public schools, to which parents were compelled to send their children at the age of four years, under certain pains and penalties. He drew up regulations for the commercial interests of his kingdom; caused bridges to be built over rivers; buoys and sea-marks to be laid down in all the dangerous parts of the coasts; and surveys to be made of the principal bays and harbours. He sent missions into the mountainous districts on the west of his kingdom, inhabited by the Laos and the Miaotse, barbarous nations whom he wished to bring into a state of civilization and good government. In short, this monarch, by his own indefatigable application to the arts and manufactures, roused, by his example, the energies of his people, and spared no pains to regenerate his country. In less than ten years, from a single vessel he accumulated a fleet of 1200 ships, of which three were of European construction. Caung-shung is, in the strictest sense of the word, a soldier, and holds the name of general in far greater estimation than that of sovereign: he is described as being brave without rashness; and fertile in expedients, when difficulties are to be surmounted. He is neither discouraged by difficulties, nor turned aside by obstacles. Cautious in deciding, but, when once resolved, prompt and vigorous to execute. In battle he is always eminently distinguished; attentive to all the officers under his command, he studiously avoids to mark out any individual as a favourite. He knows the name of almost every soldier, and delights in talking over with them of their adventures and exploits; he makes particular inquiries after their wives and children; and even enters with a degree of interest into a minute detail of their domestic concerns. To foreigners he is affable and condescending; he professes a veneration for the doctrines of Christianity, and tolerates all religions in his dominions. He observes a most scrupulous regard to the maxims of filial piety, as laid down in the works of Confucius, and humbles himself in the presence of his mother, who is still living, as a child before its master. With the works of the most eminent Chinese authors he is well acquainted; for the energy of his mind is not less vigorous than the activity of his corporeal faculties. He is represented as the main-spring of every movement that takes place in his extensive kingdom. To enable him the better to attend to the concerns of his government, his mode of life is regulated by a fixed plan. At six in the morning he rises and goes into the cold bath; at seven he has a levee with his mandarins, when the letters received on the preceding day are read, on which his orders are minuted by the respective secretaries. He then proceeds to the naval arsenal, examines the works that had been performed in his absence, and rows in his barge round the harbour, inspecting his ships of war. About twelve or one he takes his breakfast in the dock-yard, which consists of boiled rice and dried fish. At two he retires and sleeps till five, when he gives audience to the naval and military officers, the heads of tribunals or public departments, and examines what they may have to propose. These affairs generally employ his attention till midnight, when he retires to his private apartments, makes notes of the occurrences of the day, takes a light supper, passes an hour with his family, and retires to bed between two and three in the morning. We have been thus particular in drawing the character of this prince, on account of the ascendancy which he is likely to gain in that part of the East. The strength of the forces of the king in Cochin-china was, in the year 1800, as follows:

ARMY.	Men.
24 Squadrons of buffalo cavalry -	6,000
16 Battalions of elephants (200 beafts) -	8,000
30 Battalions of artillery - - -	15,000
25 Regiments of 1200 each, trained in the European manner - - -	30,000
Infantry with match-locks, &c. - -	42,000
Guards trained in European tactics -	12,000
Land forces -	113,000

MARINE.	
Artificers in the naval arfenal - -	8,000
Sailors regiftered on the fhips in the harbour	8,000
Attached to the European built veffels -	1,200
Attached to the junks - - - -	1,600
Attached to a hundred row-galleys -	8,000
Marine forces -	26,800

Making in the whole, for the land and fea-fervice, one hundred and thirty-nine thoufand eight hundred men.

Thefe military men are active and vigorous, and not encumbered with drefs; they wear pafte-board helmets, with taffels of cow-tails, dyed fcarlet; their quilted jackets and petticoats are completely Chinefe. In general, a handkerchief, tied about the head, fomewhat in the fhape of a turban, a loofe fmock-frock, with a pair of drawers, conftitute the drefs of a foldier.

Manners and Cuftoms of the Cochin-Chinefe. "As none of the houfes," fays Mr. Barrow, "were large enough for the accommodation of our party, the governor of Turon directed a fhed to be built, which was finifhed in the courfe of a few hours; the roof and fides were covered with thick clofe mats. Within this fhed was placed a row of little tables, with forms on each fide. In China it is the cuftom to cover their tables fo completely with difhes, or bowls, that no part of their furfaces can be feen; but the Cochin-Chinefe feem to have improved on the liberality of their neighbours, by not merely covering the table, but by piling the bowls in rows on each other, three or four high. Of table-linen, knives, bottles, and glaffes, they make no ufe; but before each perfon is laid a fpoon of potter's ware, and a pair of porcupine quills, or fmall fticks, like thofe ufed by the Chinefe. The contents of the bowls are preparations of beef, pork, fowls, and fifh, cut into fmall pieces, mixed with vegetables, and dreffed in foups and gravies, compofed of various materials. Neither wine, nor fpirits, nor fermented liquors of any kind, nor even water, are ferved round during the time of eating; but when dinner is over, the Chinefe *feau-choo* is handed about in porcelain cups. The governor does not fit down with ftrangers, but ufually when he entertains fuch, lies ftretched on a mattrafs at the end of a room, fmoking tobacco, or eating his areca nut, while two tall fellows agitate the air the whole time with large fans, made of the winged feathers of the Argus pheafant. The drefs of the Cochin-Chinefe is thus defcribed: they go bare-legged, and generally bare-footed; their long black hair, like that of the Malays, is ufually twifted in a knot, and fixed on the crown of the head. This, indeed, is the ancient mode in which the Chinefe wore their hair, until the Tartars, on the conqueft of the country, compelled them to fubmit to the ignominy of fhaving the whole head, except a little lock of hair behind. The houfes in general confift only of four mud walls, covered with thatch; and fuch as are fituated on low ground, or in the neighbourhood of rivers, are ufually raifed on four pofts of wood, or pillars of ftone, to keep out vermin, as well as inundations. The Cochin-Chinefe are, like the French, always gay and forever talking; the Chinefe always grave, and affect to be thinking; the former are open and familiar; the latter clofe and referved. A Chinefe would confider it as difgraceful to commit any affair of importance to a woman. Women, in the eftimation of the Cochin-Chinefe, are beft fuited for, and are accordingly entrufted with the chief concerns of the family. In Cochin-china the women are quite as gay and unreftrained as the men; but it appears to be their fate to be doomed to thofe occupations which require, if not the greateft exertions of bodily ftrength, at leaft the moft perfevering induftry. They may be feen, day after day, and from morning till night, ftanding in the midft of pools of water, occupied in the tranfplanting of rice; all the labours of tillage, and the various employments connected with agriculture, fall to the fhare of the female peafantry; while thofe in Turon, to the management of domeftic concerns, add the fuperintendence of all the details of commerce. They even affift in conftructing and keeping in repair their mud-built cottages. They conduct the manufacture of coarfe earthen-ware veffels; they manage the boats on rivers and in harbours; they carry their articles of produce to market; they draw the cotton-wool from the pod, fpin it into thread, weave it into cloth, dye it of its proper colour, and make it up into dreffes for themfelves and their families. The young men in general are compelled to enrol themfelves in the army, and fuch as are exempt from military fervice, employ themfelves occafionally in fifhing, in collecting fwallows nefts, and the *biches de mer*, among the neighbouring iflands, as luxuries for the ufe of their great men, but more particularly as articles of export for the China market; in felling timber, building and repairing fhips and boats, and fome other occupations, which however they take care fhall not engrofs their whole time, but contrive to leave a confiderable portion of it unemployed, or employed only in the purfuit of fome favourite amufement. But the activity and induftry of the women are fo unabating, their purfuits fo various, and the fatigue they undergo fo haraffing, that the Cochin-Chinefe apply to them the fame proverbial expreffion which we apply to a cat, obferving, that a woman, having nine lives, bears a great deal of killing. The men in this country, even in the common ranks of life, confider the other fex as deftined for their ufe; and thofe in the higher ftations as fubfervient to their pleafures. The number of wives, or concubines, which a man may find it expedient to take, is not limited by any law; but here, as in China, the firft in point of date claims precedence, and takes the lead in all domeftic concerns. The terms on which the parties are united are not more eafy, than thofe by which they may be feparated; the breaking of one of their copper coins, or a pair of fticks with which they eat their food, before proper witneffes, is confidered as a diffolution of their former compact, and their act of feparation. In China, as we have feen, the men have fedulously and fuccefsfully inculcated the doctrine, that a well-bred woman fhould never be feen abroad; and fo craftily have they contrived their precepts to operate, that the filly women have been prevailed on to confider a phyfical defect, which confines them to the houfe, as a fafhionable accomplifhment. In this refpect there is a total difference with regard to the Cochin-Chinefe women; they have the free ufe of their limbs and their liberty, and, by their buftling about with naked feet, they become unufually large and fpreading. The fame caufe, which in China has effected this total feclufion of the fex from fociety, and the abridgement of their phyfical powers, has produced in Cochin-china a dia-a diametrically oppofite effect, by permitting them to revel uncontrouled in every fpecies of licentioufnefs; hence they are degraded in public opinion, and confidered as beings of an inferior nature to men. Thus fituated, character becomes of little value either to themfelves or others; the confequence of which is, that women of lefs delicacy, or men of more accommodating difpofitions, are not to be met with in any part of the world than thofe in the environs of Turon bay; perhaps, however, the general character of the nation is not to be afcertained from that which prevails at a fea-port. The fingular indulgence granted by the laws of Solon, of permitting young men to difpofe of their perfonal favours, for the purpofe of enabling them to procure the articles of the firft neceffity for themfelves or their families, is fanctioned by the Cochin-Chinefe, without any limitation as to age, condition, or object. Neither the hufband nor the father feems to have any fcruples in abandoning the wife or the daughter to her gallant. This profligacy of character is not confined to the common people; it applies indeed more forcibly to the firft ranks of fociety. There is, however, but little that is prepoffeffing in the general appearance of the Cochin-Chinefe. The women have but flender pretenfions to beauty; yet the want of perfonal charms is in fome degree compenfated by a lively and cheerful temper. Both fexes are coarfely featured, and their colour is very dark; they have the univerfal cuftom of chewing areca and betel, which, by reddening the lips, and blackening the teeth, gives them an appearance ftill more unfeemly than nature intended. The drefs of the women is by no means fafcinating. A loofe cotton frock, of a brown or blue colour, reaching down to the middle of the thigh, and a pair of black nankeen trowfers, made very wide, conftitute in general their common clothing. With the ufe of ftockings and fhoes they are wholly unacquainted; but the upper ranks wear a kind of fandals, or loofe flippers. As a holiday drefs, on particular occafions, a lady puts on three or four frocks at once, of different colours and lengths, the fhorteft being uppermoft. Their long black hair is fometimes twifted into a knot, and fixed on the crown of the head, and fometimes hangs loofe in flowing treffes down the back, frequently reaching to the very ground. Short hair is not only confidered as a mark of vulgarity, but an indication of degeneracy; the drefs of the men has little, if any thing, to diftinguifh it from that of the other fex, being chiefly confined to a jacket and a pair of trowfers. Some wear handkerchiefs tied round the head, others have hats or caps, formed for protecting their face againft the rays of the fun; for which purpofe they alfo make ufe of umbrellas of ftrong China paper, or fcreens of leaves, or fans made of feathers. Confonant with the appearance of their mean and fcanty clothing, are their lowly cabins of bamboo. There is, however, fuch a vaft difference in the circumftances under which an European and an inhabitant of a tropical climate are fituated, that the former, who for the firft time finds himfelf among the latter, will be very apt to fall into error in attempting to form a comparative eftimate of their refpective conditions. To the one, fuel and clothing, and clofe and compact lodging, are effential, not only to his comfort, but to his exiftence; to the other, fire is of no father ufe than a few embers to boil his rice, or to prepare an offering for his god. Clofe, thick clothing, fo far from being a comfort, would be to him the moft inconvenient of all incumbrances. Even the little which he occafionally finds it expedient to ufe, he frequently throws afide; for where nakednefs is no difgrace, he can at all times, and in all places, accommodate his drefs to his feelings and his circumftances. In the vicinity of Turon bay, there are only a few villages, in the largeft of which the number of houfes do not exceed 100, and thefe chiefly thatched. The cottages of Turon are in general fnug and clean, and fufficiently compact to protect the inhabitants from the heat of the fun at one feafon, and the heavy rains at the other. There feems to be no want in the market of either cotton or filk ftuffs for clothing; and the country produces a great variety and abundance of articles, which contribute to the fuftenance of the multitude, as well as to the luxuries of the higher orders of the people. Almoft every kind of domeftic animal, except fheep, appears to be very plentiful. In Cochin-china they have bullocks, goats, fwine, buffaloes, elephants, camels, and horfes. In the woods are found the wild boar, tiger, and rhinoceros, with plenty of deer; they account the flefh of the elephant a great dainty, and their poultry is excellent. They pay little attention to the breeding of bullocks, as the tillage of their land is performed by buffaloes, and their flefh is not efteemed as food. The fea, as well as the land, is a never-failing fource of fuftenance to thofe who dwell on the coaft. Moft of the general marine worms, diftinguifhed by the name of *mollufca*, are ufed as articles of food by the Cochin-Chinefe. All the gelatinous fubftances derived from the fea, whether animal or vegetable, are confidered by them the moft nutritious of all aliments; and, on this principle, various kinds of fea-weeds, particularly the *fuci* and *ulvæ*, are included in their lift of edible plants. The Cochin-Chinefe collect likewife many of the fmall fucculent, or flefhy plants, which are ufually produced on falt and fandy marfhes, which they either boil in their foups, or eat in a raw ftate, to give fapidity to their rice, which with them is the grand fupport of exiftence. In Cochin-china they are almoft certain of two plentiful crops of rice every year, one of which is reaped in April, the other in October. Fruits of various kinds, as oranges, bananas, figs, pine-apples, pomegranates, and others of inferior note, are abundantly produced in all parts of the country. They have very fine yams, and plenty of fweet potatoes. Their fmall breed of cattle does not appear to furnifh them with much milk, but of this article they make a fparing ufe, even with regard to their young children. Children, till the age of feven or eight years, go entirely naked, and their food feems to confift chiefly of rice, fugar-cane, and water-melons. The mafs of the people in Cochin-china, like the common Chinefe, have but two meals in the day, one about nine or ten in the morning, and the other about fun-fet; and thefe are ufually taken in the dry feafon, before the doors of their cottages, upon mats fpread in the open air.

Amufements. The Cochin-Chinefe are very fond of theatrical amufements; the actors are bufily engaged in their performances the whole day, proceeding, apparently, with as much ardour when there are few or even no fpectators prefent, as when there are many. Being hired for the day, a crowded or a thin audience makes but little difference to the performers, all their concern being the receit of their pay on the finifhing of their labour. One of thefe exhibitions has been defcribed by Mr. Barrow. "In the farther divifion of the buildings," fays he, "a party of comedians was engaged in the midft of an hiftorical drama when we entered; but on our being feated they broke off, and coming forward made before us an obeifance of nine genuflexions and proftrations, after which they returned to their labours, keeping up an inceffant noife and buftle during our ftay. The horrible crafh of the gongs, kettle-drums, rattles, trumpets and fqualling flutes, were fo ftunning and oppreffive, that nothing but the novelty of the fcene could have detained us for a moment. The moft entertaining part of the exhibition was a fort of interlude, performed by three young women, for the amufement as it fhould feem of the principal actrefs, who ſat as a ſpectator in the character of ſome ancient queen; whilſt an old eunuch, very whimſically dreſſed, played his antic tricks, like a buffoon, in an harlequin entertainment. The dialogue was light and comic, and occaſionally interrupted by cheerful airs, which concluded with a common chorus. Theſe airs, rude and unpoliſhed as they were, appeared to be regular compoſitions, and were ſung in exactly meaſured time. The voices of the women were ſhrill and warbling, but ſome of their cadences were not without melody, and the inſtruments at each pauſe gave a few ſhort flouriſhes, till overpowered by the deafening gong. At each repetition of the chorus, the three Cochin-Chineſe graces diſplayed their fine ſlender ſhapes in the mazy dance, in which, however, the feet were the leaſt concerned. By different geſtures of the head, body, and arms, they aſſumed a variety of figures, and all their motions were exactly adapted to the meaſure of the muſic. No entrance money is ever expected in the theatre of China, or Cochin-china. The actors are either hired to play at private entertainments, at a fixed ſum for the day; or they exhibit before the public in a temporary ſhed entirely expoſed in front. On ſuch occaſions, inſtead of cheering the performers with empty plaudits, the audience throw among them pieces of copper money." At Cochin-china football with a bladder; leaping over an horizontal pole, and other acts of agility are practiſed. The men amuſe themſelves in fighting cocks, and young boys, in imitation of their elders, train quails, ſmall birds, and even graſshoppers to tear each other in pieces; and in every corner of the ſtreets gameſters may be ſeen playing at cards, or throwing of dice. But what will moſt aſtoniſh an European, is the ſight of a party of young men keeping up a ſhuttlecock in the air, by ſtriking it with the ſoles of the feet. Nothing indeed can exceed the activity and energy of the men in Cochin-china; but, active as they are, in the uſe of their feet, their manual dexterity is not leſs remarkable. Jugglers and conjurors, and poſture-makers, are continually exerciſing their reſpective arts for the amuſement of the crowd, and for their own advantage; and thoſe who do not openly practiſe juggling as a profeſſion, are equally as expert in the art of picking pockets. They are all, from the higheſt to the loweſt, moſt importunate beggars, craving without the leaſt ceremony, for every thing that may ſuit their fancy; they are neither ſatisfied with a ſimple denial, nor even with obtaining what they aſk, but generally become more urgent in their demands, in proportion to the liberality of the giver, and what they cannot obtain by begging, they uſually endeavour to procure by ſtealing.

Arts, Manufactures, &c. That particular branch of the arts in which the Cochin-Chineſe may be ſaid to excel at the preſent day, is naval architecture, for which they are not a little indebted to the ſize and quality of their timber. Their row-gallies for pleaſure are remarkably fine veſſels, from 50 to 80 feet in length, and they are ſometimes compoſed of five ſingle planks, each extending from one extremity to the other. The edge is mortiſed, kept tight by wooden pins, and bound firm by twiſted fibres of bamboo, without either ribs or any kind of timbers. At the ſtem and ſtern they are raiſed to a conſiderable height, and are curiouſly carved into monſtrous figures of dragons and ſerpents, ornamented with gilding and painting. A number of poles, bearing flags and ſtreamers, pikes ornamented with tufts of cows' tails painted red, lanterns and umbrellas, and other inſignia, denoting the rank of the paſſenger, are erected at each end of the boat. The veſſels that are employed in the coaſting trade, the fiſhing craft, and thoſe which collect ſwallows-neſts among the iſlands, are of various deſcriptions: many of them covered with ſheds of matting, under which whole families conſtantly reſide. Their foreign traders are built on the ſame plan as the Chineſe junks; the form and conſtruction of which are entitled to but little reſpect, except from the antiquity of the invention. As theſe veſſels were never intended for ſhips of war, ſecurity rather than ſpeed has always been the object of the owner. And as no great capitals are employed in trade, and the merchant is both owner and navigator, a limited tonnage is ſufficient for his own merchandize; the veſſel is therefore divided into diſtinct compartments, ſo that one ſhip may ſeparately accommodate many merchants. The bulk heads, by which the diviſions are formed, conſiſt of planks two inches thick, and ſo well caulked and ſecured as to be completely water tight. A ſhip thus fortified with croſs-bulk heads, may ſtrike on a rock, and yet ſuſtain no ſerious injury; a leak ſpringing in one diviſion of the whole will not be attended with any damage to the articles placed in another; and by the ſhip being ſo well bound together, ſhe is firm and ſtrong enough to ſuſtain a more than ordinary ſhock. In the neighbourhood of Turon are ſeveral plantations of ſugar and tobacco. The juice of the former having undergone a partial refinement, is exported to China in cakes, which in colour, thickneſs, and poroſity, reſemble the honeycomb; the latter is conſumed in the country, as all degrees, of every age and ſex, indulge in the habit of ſmoaking. The face of the country exhibits but feeble marks of tillage, and arts and manufactures are evidently in a languiſhing ſtate. The cottages contain little furniture, and that little is of rude conſtruction, as if intended only for temporary uſe. The matting that covers the floor is ingeniouſly woven in different colours. Their domeſtic utenſils conſiſt chiefly of an earthen ſtove, an iron pot to boil rice, a pan ſomewhat in the ſhape of a watch-glaſs, to fry their vegetables in oil, and a few porcelain cups or bowls. Their veſſels of caſt iron are equal in quality to thoſe of the Chineſe, but their earthen ware is very inferior. They work in metal with a tolerable degree of neatneſs, and their articles of fillagree are equal to thoſe of the Chineſe. In fact both the one and the other poſſeſs quick and comprehenſive talents, and under proper encouragement are already in that advanced ſtage to make a very rapid progreſs in the arts, ſciences, and manufactures. Theſe, however, do not appear to be in a ſtate of progreſſive improvement: but under every diſadvantage their ingenuity occaſionally breaks forth in a ſurpriſing manner. There is in all oriental governments a radical defect, which no advantages of ſoil or climate, or other favourable circumſtances can compenſate, and which muſt for ever operate againſt their attaining the character and condition of a great and happy people. This defect ariſes from the want of a permanent ſecurity to property.

The ſituation of Cochin-china is well adapted to commerce; its vicinity to China, Tunquin, Japan, Cambodia, Siam, the Malay coaſt, the Philippines, Borneo, the Moluccas, &c. renders the intercourſe with all theſe countries eaſy and expeditious, the commodious harbours formed on the coaſt, particularly that of Turon, afford a ſafe retreat for ſhips of any burthen, during the moſt tempeſtuous ſeaſons of the year. No country in the Eaſt produces richer, or a greater variety of articles proper for carrying on an advantageous commerce; ſuch as cinnamon, pepper, cardamoms, ſilk, cotton, ſugar, Agula-wood, Japan-wood, ivory, &c. Gold is obtained almoſt pure from the mines; and gold in duſt has been brought at different periods from the mountains, and bartered by the rude inhabitants for rice, cloths, and iron. From them alſo the Agula and Calamboe woods are procured, together with quantities of wax, honey, and ivory. Silver mines have been alſo lately diſcovered; and both gold and ſilver are uſed in ingots, as in China. The commodities, for

which

which there is the greateſt demand at Cochin-china, are ſaltpetre, ſulphur, lead, fine cloths, and barred or flowered chints. Pearls, amber, and coral were formerly in great requeſt. The principal exports of this country are ſilks, ſugar, which is excellently purified by a proceſs deſcribed by Sir George Staunton, ebony, and Calamboe wood, edible birds' neſts, which are found in great plenty on the iſlands that are ſituated near the coaſts of Cochin-china, and which are eſteemed a luxury in China, gold in duſt or bars, and copper, and porcelain, tranſported thither from China and Japan. It has been ſuggeſted that a commercial connection with Cochin-china might prove very beneficial to this country. The drain of ſpecie from the company's ſettlements in India, is become a matter of ſuch ſerious import, that any plan for reſtraining and counteracting this growing evil demands attention; and it has been thought that a ſettlement in Cochin-china would conduce to this important and deſirable purpoſe, as well as be productive of many other advantages; the productions of Cochin-china, which are in great demand among the Chineſe, might with eaſe be brought to centre with us, if we had a ſettlement and a confirmed influence in the country. Purchaſed with the ſtaples of India and of Europe, Turon would become the emporium for them, where our ſhips bound to Canton, from which it is only five days ſail, might call and receive them. It would prove a ſaving of ſo much ſpecie to Great Britain or India, as the value of the commodities amounted to in China. In a few years, there is reaſon to believe, a very conſiderable inveſtment might be provided. A ſettlement in Cochin-china would give us a ſuperior advantage both to the Dutch and the Spaniards, not only as its ſituation is nearer, but as the Chineſe are more accuſtomed to reſort thither. Colonies of Chineſe have, from time to time, emigrated from the parent country, and fixed their abode in different parts of Cochin-china. Theſe have a correſpondence in every ſea-port of the empire; and by their means, teas, china-ware, and various other articles, that are the objects of our commerce with China, might be imported in junks to our own ſettlements, equally good in quality, and cheaper, as the Chineſe are exempted from the exorbitant duties levied on foreigners. Some of the beſt workmen might be encouraged to ſettle in Cochin-china, and under proper direction, manufactures might be carried on to as great a degree of perfection as in China itſelf. The intercourſe between Japan and Cochin-china might be renewed, and we might participate in a trade for many years monopolized by the Dutch. An advantageous trade might be carried on with the Philippine iſlands, and goods for Madras and Bengal, introduced among them by means of the junks, for the conſumption of Spaniſh America. The Siameſe and Cambodians would bring the produce of their reſpective countries, and barter or ſell it for ſuch articles as they wanted from Cochin-china, and among them a ſale might probably be found for quantities of Bengal cloths. The gold mines of this country, of which we have already taken notice, would promote and enrich ſuch an eſtabliſhment in Cochin-china, the expediency and utility of which have now been ſuggeſted. Beſides the commercial advantages likely to reſult from ſuch a ſettlement, it would be attended with others of a political nature. Turon-bay would not only afford a ſecure retreat to our Indiamen, in caſe of loſing their paſſage to China, but from thence we might intercept the fleets of any hoſtile power, either going to, or returning from that country. We ſhould thus become formidable neighbours to the Dutch, and to the Spaniards, and in the event of a war with either of them, attack, with advantage, their moſt valuable ſettlements.

The Japaneſe is the only current money in Cochin-china: it is paid or received by weight; the money of the country, which is of copper, is as large as our common counters, of a round figure, and has a hole in the middle, by which it may be ſtrung in the ſame manner as beads. Three hundred pieces are put on one ſide, and 300 on another, which paſs in Cochin-china for a thouſand; becauſe in 600 there are found 10 times 60, which make a century among almoſt all the people of the Eaſt. In this country merchants are liable to be much deceived with regard to the value of money; becauſe the pieces are unequal in figure and quality, and their value is regulated by a few characters that are ſtamped upon them, which are not eaſily aſcertained; accordingly merchants, without the aſſiſtance of honeſt and ſkilful people, are liable to great impoſition, more eſpecially as the traders of Cochin-china value themſelves on being able to cheat an European.

The Language and Religion of the Cochin-Chineſe. The Cochin-Chineſe have effectually preſerved the written characters of the Chineſe language, but the ſpoken language has undergone a very conſiderable change, which is not ſurpriſing, ſince the inhabitants of the northern and ſouthern provinces of China are unintelligible to each other; though it has been altered, it does not appear to have received any improvement. By a compariſon of a ſhort catalogue of Chineſe words, taken from Mr. Barrow's excellent work on Cochin-china, with their ſynonyms, in the Cochin-chineſe language, an idea may be formed how far the two ſpoken languages reſemble or differ from each other.

The Cochin-Chineſe have introduced the conſonants *b, d, r,* which they pronounce without the leaſt difficulty, though a Chineſe cannot by any exertion articulate a ſyllable into which one of theſe enters. In the conſtruction of phraſes, there is alſo a conſiderable difference between the two languages. In forming the plural of the perſonal pronouns, the Chineſe make uſe of the ſyllable muen, *many*, as,

ngo,	ne,	ta,
I,	thou,	he,
ngo-muen,	ne-muen,	ta-muen,
we,	ye,	they,

But the Cochin-Chineſe employ the ſyllable chung, *all*, as,

tooi,	bai,	no,
I,	thou,	he,
chung-tooi,	chung-bai,	chung-no,
we,	ye,	they.

To the Cochin-Chineſe, "we found leſs difficulties," ſays Mr. Barrow, "in making ourſelves intelligible, than we had to encounter with the grave and ſolemn Chineſe, whoſe dignity would be thought to ſuffer debaſement by their condeſcending to employ the pencil in delineating objects, notwithſtanding its alliance with their mode of writing; or by attempting to indicate, by ſigns and geſtures, ſuch ideas as are capable of being interchanged without the aid of language. This was by no means the caſe with the Cochin-Chineſe, who always ſeemed anxious to enter into our views, and to facilitate a mutual underſtanding."

The *religion* of the Cochin-Chineſe, like that of almoſt all the oriental nations, is a modification of the doctrine of Budha, but more ſimple, and leſs diſguiſed with the myſteries and machinery of oracular worſhip, than that which is practiſed popularly in China. From a ſentiment of gratitude to the benevolent and bountiful ſpirit, the Cochin-Chineſe manifeſt their piety, by offering to the image of the protecting deity the firſtlings of their living flocks, and of the fruits of the earth. The firſt ears of rice, the firſt cup of ſugar, or whatever the nature of the produce may be, is taken to the ſhrine which contains the ſacred image, and is there depoſited with becoming reverence, as an humble acknowledgment of the divine goodneſs. Mr. Barrow was preſent at an offering of this kind, which he thus deſcribes: "I obſerved a perſon in a long coloured robe reaching to the ground, his head bare and cloſely ſhaved, marching with a kind of meaſured ſtep, and followed by a few of the peaſantry. On arriving at the foot of the tree, they all halted, juſt at the head of the main trunk (for it was a ſpecies of banian tree, called *dea* in Cochin-china, whoſe branches take root and become ſtems). I obſerved a large cage of latticed work, with a pair of folding doors, fixed within two boughs, and partly hidden by the foliage. Within was a wooden figure of Budha, of the ſame corpulent ſhape, and in the uſual ſitting poſture as he is repreſented in the temples of China. A little boy, attending on the prieſt, ſtood cloſe before him, with a burning coal on a brazen diſh. One of the peaſants carried a ladder of bamboo, which he placed againſt the tree, and another mounting it, depoſited in the cage before the idol, two baſons of rice, a cup of ſugar, and one of ſalt. The prieſt in the meantime, with arms extended, and eyes turned towards heaven, muttering ſomething in a low tone of voice, when the man who had carried the ladder fell on his knees, and nine times proſtrated his body to the ground, according to the cuſtom of the Chineſe. Several women and children remained at a diſtance, as if forbidden to approach too near; though as prieſteſſes are ſaid to be common in this country, it is not probable there was any reſtriction on account of the ſex." The Cochin-Chineſe are extremely ſuperſtitious, and their devotional exerciſes, like thoſe of the Chineſe, are more frequently performed with a view of averting an ideal evil, than with the hope of acquiring a poſitive good; or, in other words, the evil ſpirit is more dreaded than the good one is revered. In various parts of the country are erected large wooden pillars, not only for the purpoſe of marking the ſpot where ſome great calamity may have happened, but as a propitiation to the evil ſpirit, by whoſe influence it is ſuppoſed to have been occaſioned. So, when an infant dies, the parents are ſuppoſed to have incurred the diſpleaſure of ſome malignant ſpirit, which they endeavour to appeaſe by offerings that they imagine to be moſt acceptable to the angry divinity. Beſides the ſpontaneous offering, which individuals conceive it neceſſary to make on various occaſions, there is a yearly contribution levied by government, for the purpoſe of ſupporting a number of monaſteries, in which the prieſts invoke the deity for the public welfare. This contribution conſiſts of produce in kind, as rice, fruits, ſugar, &c.; in lieu of which, in towns, are collected money, metals, and clothing. The prieſts here, as in China, are reckoned the beſt phyſicians, but their art lies more in charms and facinations, than in the judicious application of ſanative drugs.

COCHINEAL, *Coccus cacti*, Linn. See Coccus *Cacti*. The ſubſtance known in commerce by the name of cochineal, which is the moſt precious of all our dyeing drugs, affording the ſcarlet crimſon, and many other valuable dyes, and from which the fineſt carmine is generally prepared, is in the form of hemiſpherical ſhrivelled grains, about an eighth of an inch long, of a deep reddiſh-purple colour, and covered more or leſs with a white down: they are very light, and eaſily rubbed to powder between the fingers. The Spaniſh merchants diſtinguiſh at leaſt two kinds, the beſt, or domeſticated, called *grana fina*, or fine grain, and the wild, or *grana ſylveſtra*; of theſe, the latter is not more than half the ſize of the former, and is covered with a much longer down; on which account it always bears a much lower price in the market.

The cochineal inſect is a native of Mexico, and was in common uſe among the inhabitants as a dyeing drug when the Spaniards firſt came into the country; ſince that period its uſe has become more and more general, not only in Europe, but in various parts of Aſia, and, as almoſt the whole of this valuable commodity is ſtill raiſed in Mexico, Peru, and the adjoining Spaniſh ſettlements, it becomes every year an object of more ſedulous cultivation than before.

The beſt and fineſt cochineal, and, indeed, by far the greateſt proportion of that conſumed in Europe, is brought to us from Mexico. The principal diſtricts where it is bred are Oaxaca, Tlaſcala, Chulula, Neuva Gallicia, and Chiapa, in New Spain, but it is in Oaxaca that the greateſt quantities are produced, where the cultivation of this little inſect has long given employment and been an object of commerce to the native Mexicans. According to Ulloa it is likewiſe produced at Hambatia, Loja, and Tucuman in Peru. It has been introduced into St. Domingo, and the Braſils alſo.

The wild cochineal (grana ſylveſtra) feeds upon moſt of the ſpecies of cacti that are natives of Mexico, requires no particular care or attendance, and may be gathered ſix times in in the year, there being fo many generations of this infect in a twelvemonth: the time of collecting the cochineal is juft before the female produces its young, as the animal perifhes immediately afterwards. The cultivated cochineal (grana fina), called alfo *Meftique* from a Mexican province of that name, is the product of flow and progreffive improvement in the breed of the wild cochineal, and is found only in the gardens and plantations of Mexico, where, provided with its choiceft food and fheltered from the inclemencies of the feafons, it attains nearly double its original fize. This feeds only on one fpecies of cactus, the cochenilifer or nopal, and produces only three broods in the year. Its management is fimple, but requires inceffant attention. At the third annual gathering of cochineal, a certain number of females are left adhering to branches of the nopal, which are then broken off and kept carefully under cover during the rainy feafon; when this is over, the ftock of cochineal, thus preferved by each cultivator, is diftributed over the whole plantation of nopals, where they foon multiply with great rapidity. In the fpace of two months. the firft crop is gathered by detaching the infects with a blunt knife, after which they are put into bags, and dipped in hot water to kill them, and finally dried in the fun, by which they lofe about two-thirds of their weight. This kind is alfo much more abundant in colouring matter, in which, indeed, its fuperiority over all other kinds confifts; fince, from the experiments of the French academicians, the grana fylveftra of Mexico, and the cochineal of St. Domingo, afforded colours equal in brilliancy, though not in quantity, to the meftique or grana fina. The cochineal of Brafil alfo, according to Bancroft, is not inferior in quality to the fine grain of Mexico, though it contains only half the quantity of colouring matter. The proportion of colouring matter contained in equal portions of the cultivated cochineal, of the wild cochineal of Mexico, and of an inferior kind from St. Domingo, is, according to Berthollet, as eighteen, eleven, and eight.

In time of peace, the cochineal of Mexico is almoft exclufively fent from Vera Cruz to Cadiz, whence it is diffufed all over Europe; but in time of war a contraband trade is carried on to various parts of America and the Weft Indies, whence this country is chiefly fupplied.

The quantities of fine cochineal imported into Spain in the years 1788, 1789, and 1790, amounted to 11,000 bags, weighing 200lb. each, and making together 2,200,000lb. weight; and between the 1ft of January, 1791, and the 1ft of October in the fame year, the importations had exceeded 2000 bags. From accurate calculations it appears that the average quantity of fine cochineal, annually confumed in Europe, amounts to about 3000 bags, or 600,000lb. weight, of which 1200 bags, or 240,000lb. may be confidered as the prefent annual confumption of Great Britain: a greater quantity comes, indeed, into the kingdom, but the furplus is again exported to other countries. The attention of the Eaft India company has been lately directed to the production of this infect, though hitherto with but partial fuccefs. It is very fmall, not very abundant in colouring matter, and inferior in quality to that of New Spain. It is ufed only for the coarfeft goods, and fold from 3*s*. 6*d*. to 5*s*. per pound. From 8 to 10,000 lb. are annually brought to this country. See Coccus Cacti.

Cochineal retains fome traces of its original form, even in its dried ftate; and though Europe for a long time confidered it as the feeds of an Indian plant, it is eafy to felect from a parcel fome infects in which the round or convex back, with fmall tranfverfal furrows and flat belly, are readily difcovered. Its external or commercial characters differ confiderably; it is diftinguifhed by the dealers chiefly by its colour and fize. 1. The large black, or deep purple, of bright hue, is preferred to all others. Its value decreafes with its fize and luftre. 2. The large filver grey, though held in lefs eftimation here, is, in general, equal to the former. It is preferred by the German buyers, to whom it is fold fomewhat lower than the preceding, and from which it differs only in the lefs removal of that white farinaceous powder with which the infects, in their natural ftate, are covered. 3. The fmall white or filvery cochineal is held in little eftimation, and fold at very inferior prices. Cochineal duft is fometimes found in the market, and alfo the fmall, or mutilated grains, feparated by the fieve from the larger, and known by the name of *Granilla*. All thefe kinds are liable to adulteration with various fubftances, but more efpecially with a pafte, which is fometimes managed fo dexteroufly as to deceive the beft judges, without very particular examination.

The ufe of cochineal was known to the Mexicans before the invafion of the Spaniards. It was the beauty of its colour, as difplayed in their furniture, ornaments, and cotton cloth, which firft directed the attention of their conquerors towards this precious infect. From the reports made to the Spanifh miniftry on this fubject, orders were iffued to Cortes, in the year 1523, to take meafures for multiplying this valuable commodity, and confiderable quantities, raifed by the induftry of the natives, were foon afterwards fent to Spain. Although it was for fome time fuppofed to be the berry or feed of a vegetable; it was at length, however, afcertained that thefe grains were the females of a particular fpecies of infect, called by naturalifts "Coccus cacti," and of the fame genus as the "kermes" (Coccus ilicis, Linn.). See Coccus.

It is probable that alum was the only mordant ufed for fixing the cochineal dye for fome time after its introduction into Europe. The Mexicans alfo employed the fame fubftance, as appears from the teftimony of the Spanifh hiftorian, Herrara. The colour afforded by cochineal with the aluminous mordants is crimfon, and, indeed, previous to the difcovery of the ufe of tin, this feems to have been the only colour analogous to fcarlet that was known. Drebbel, or, as fome fay, Kufter, or Keffler, a German chemift, firft difcovered the effect of the folution of tin in exalting the cochineal dye. He brought his fecret to London about the year 1643; and the firft eftablifhment for dyeing fcarlet in this country appears to have been at Bow, whence it obtained, for a long time, the name of the Bow-dye. The procefs was known in Holland foon after the difcovery was made, and in France alfo, where it was practifed by the famous Gobelins, who received information from a Flemifh painter, to whom it had been communicated by Kufter himfelf. For the details of this operation, and the fucceffive improvements down to the prefent time, we refer our readers to the article Scarlet-*Dye*.

Cochineal, when thoroughly dry, if kept in a dry place, and in clofe packages, may be preferved many years without alteration. Hellot tried fome 130 years old, and found it equal in quality to the frefh infects.

The colouring matter of cochineal may be extricated either by water or alcohol. The alcoholic folution is of a deep crimfon colour, and, on evaporation, leaves a tranfparent refiduum of a deep red, which has the appearance of a refin, and which affords by diftillation the products of animal fubftances. The aqueous folution or decoction of cochineal is of a crimfon colour, bordering on purple, when viewed by tranfmitted lights; and this, if evaporated flowly to the confiftence of an extract, and then digefted in alcohol, communicates

municates to this menſtruum a colour ſimilar to the preceding ſpirituous ſolution, a reſiduum of the colour of wine-lees being left behind. This affords, by deſtructive diſtillation, the products of animal ſubſtances.

The aqueous decoction of cochineal, if mixed with a little ſulphuric acid, aſſumes a red colour, inclining to yellowiſh, or orange hue, and a ſmall quantity of a fine red precipitate is thrown down. Muriatic acid produces nearly the ſame change of colour, but occaſions no precipitate. A ſolution of tartar, and, indeed, all acids, change the cochineal decoction to a yellowiſh red, and a ſmall quantity of a pale red precipitate is ſlowly depoſited: the ſupernatant liquor is yellow, but on the addition of a little alkali it becomes purple, the precipitate being at the ſame time re-diſſolved. Alum brightens the colour of the infuſion and gives it a redder hue; a crimſon precipitate is depoſited, and the ſupernatant liquor retains a ſimilar tinge. A mixture of alum and tartar produces a brighter and more lively colour, inclining to yellow; and a precipitate is thrown down, but much paler, and leſs in quantity than where alum alone is uſed. Nitro-muriate of tin throws down a crimſon ſediment in conſiderable abundance, not a particle of colouring matter remaining in the liquor.

On adding a ſolution of tartar, and afterwards of tin, to the infuſion of cochineal, a roſe-coloured precipitate is formed more quickly than in the preceding experiment. The ſupernatant liquor retains a tinge of yellow.

Cochineal, boiled with half its weight of tartar, affords a decoction more inclining to red, and not ſo deep as when boiled with water only. With the ſolution of tin, however, it affords a more abundant precipitate, and of a more intenſe colour. The extraction of the colouring particles of cochineal, therefore, is favoured by the action of tartar, though the liquor appears much paler than the ſimple aqueous ſolution.

The ſulphate of iron forms a brown coloured purple, or browniſh violet precipitate; and the ſupernatant liquor is of a dilute yellowiſh brown. The ſulphate of zinc forms a deep purple, or deep violet; and the acetate of lead a purple-violet precipitate, leſs deep than the preceding; the liquor in both caſes being perfectly colourleſs.

The ſulphate of copper changes the colour of the decoction to violet, and a ſmall ſediment of the ſame colour ſlowly ſubſides.

Berthollet remarks a diſtinctive character in the colouring matter of cochineal, compared with that of madder, treated with the ſame re-agents. Both ſpecies of colouring matter acquire a yellow colour from acids; but if the particles of cochineal be ſeparated by a ſubſtance, which precipitates them from the acid liquor they are diſſolved in, they reappear with their natural colour little changed, whilſt thoſe of madder retain a yellow or fawn-coloured hue. On this account the ſolutions of tin, which retain a great exceſs of acid, and are ſo eminently uſeful in exalting the colour of cochineal, are uſed with little ſucceſs with madder; probably as Mr. Berthollet ſuppoſes, becauſe the combination of the oxide of tin with the colouring matter of madder, retains a larger portion of acid than it does when combined with the colouring matter of cochineal.

We have before obſerved, that the natural colour of cochineal is crimſon, and that, till the diſcovery of the uſe of the ſolution of tin, the colour now called ſcarlet was unknown. The production of this colour was aſcribed to the nitro-muriate of tin only, and more eſpecially to the action of the nitrous acid of that ſolution, with little or no reference to the agency of the tartar, which was always employed in the operation. We are indebted to Bancroft for the correction of this error, and for a ſeries of experiments on the action of other metallic and earthy ſolutions, with the colouring matter of cochineal on woollen.

From theſe experiments it appears, that cochineal, with the nitro-muriate of tin, or common dyers' ſpirits, produced a crimſon only, but with the addition of tartar a good ſcarlet.

Cochineal, with a ſolution of tin in muriatic acid, dyed a beautiful crimſon, and with a ſolution of that metal, by a mixture of tartar and muriatic acid, a beautiful ſcarlet.

Cochineal, with tin calcined by the long continued action of ſulphuric acid, dyed a ſalmon colour, and, with a recent ſolution of tin, a reddiſh ſalmon colour, inclining a little to the crimſon. A ſolution of tin, in equal parts of nitric and ſulphuric acids mixed, afforded a ſimilar colour.

Tin, diſſolved by the pure acid of tartar, dyed with cochineal a very beautiful ſcarlet, inclining a little to the aurora.

Tin very readily diſſolves by pure citric acid, and even by lemon juice; and the ſolution, newly made, dyes with cochineal a moſt beautiful ſcarlet, inclining, like the preceding, a little to the aurora. The citric acid with tin acts, at leaſt as efficaciouſly as that of tartar, in yellowing the cochineal crimſon; nothing, ſays Dr. Bancroft, can exceed the beauty of ſcarlet dyed with the citrate of tin.

The ſolution of tin in vinegar afforded a ſcarlet inclining a little to the crimſon.

The phoſphate of tin produced an aurora, and the fluate of tin a very good ſcarlet.

With other baſes cochineal gave the following colours to woollen:

With nitro-muriate of platina, a red, and of gold a reddiſh brown.

With nitrate of ſilver a dull red, and with muriate of ſilver a lively reddiſh-orange.

With the acetate of lead, a purple, inclining to violet; and with nitrate of lead, a delicate lively colour, between the red and cinnamon, but inclining moſt to the former.

With the ſulphate, nitrate, muriate, and acetate of iron, cochineal produces a dark-violet, and even a full black, when employed in ſufficient quantity.

All the preparations of copper appear to debaſe the colouring matter of cochineal, as do thoſe of mercury in a ſtill greater degree; moſt of theſe, whilſt they degrade the colour, ſeem to annihilate a portion of it.

With the nitrate and muriate of zinc, and various ſolutions of biſmuth, cochineal produces different ſhades of lilac. Cobalt and nickel alſo afford various ſhades of lilac and purple. The ſulphate of mangan eſe an orange, and the nitrate of mangan eſe a colour reſembling a madder red.

It has been before obſerved, that, with the aluminous mordants, cochineal affords its natural colour, or crimſon. Dr. Bancroft has alſo examined the effects of other earthy ſolutions.

Lime water, with cochineal, dyes a purple, which took but ſlowly, and required long boiling.

Sulphate of lime a full dark red, and nitrate of lime a lively red, approaching to ſcarlet, and muriate of lime a purple.

The ſolutions of barytes and of magneſia, afforded various ſhades of lilac, and even the ſolution of ſilex in cauſtic alkali, precipitated by the addition of an acid, affords a full rich pleaſing purple, which proved ſufficiently durable.

The foregoing experiments repeated on ſilk gave leſs advantageous reſults. Cochineal, indeed, with the aluminous baſis, dyes the crimſon colour as well and as durably on ſilk as on wool. The modes of producing this are well known,

known, and will be treated of hereafter; but in general, with the other earthy and metallic bases, cochineal produced similar but much paler colours than on wool.

The little disposition manifested by the colouring matter of cochineal to unite with cotton, and the celebrated experiment of Mr. Dufay to illustrate this, are well known. He caused a piece of cloth to be manufactured with a woollen web and cotton woof, and having subjected it to the ordinary process of dyeing scarlet, found that the wool had taken a most beautiful scarlet, whilst the cotton remained perfectly white. Subsequent experiments have shown that this effect arises not from the total want of affinity between the colouring particles of cochineal united to tin, and the fibres of cotton, but from a striking and powerful difference in the force with which the colouring matter is attracted by the two substances. When cotton *alone* is subjected to the same process, it takes a scarlet colour more slowly indeed, and paler than that imbibed by woollen, yet sufficient to prove its disposition to such union, when not counteracted by more powerful affinities. When cotton and wool, however, are *jointly* subjected to the operation of scarlet dyeing, the latter, by its strong attraction, draws, and exclusively appropriates to itself, all the colouring matter in the vessel before the cotton has had time to engage any part of it. It is owing to this weaker attraction between the fibres of cotton and the scarlet dye, that this latter is so much less permanent on cotton than on wool; and it is also from this want of sufficient attraction that the cochineal colour is found to take most beneficially on cotton, when the basis has first been applied separately.

Cochineal is sometimes used by calico printers in topical dyeing, but more frequently in the preparation of those colours for the pencil, which are described under the article Colour-*making*.

The mordants used for cochineal are those employed with madder. The acetate of iron, or iron liquor for black, diluted solutions for various shades of purple or lilac, and mixtures of the acetates of iron and alumine for chocolates, blooms, &c. &c.

With the common aluminous mordant, printed and rinsed off the same as for madder red, cochineal affords a bright and beautiful crimson. It is, however, much less fixed than madder, and cannot support repeated washing and exposure. It is applied chiefly on fine cloth and delicate muslins, when the solidity of the colour is oftentimes an object of less consideration than its beauty. An addition of one-tenth, or fifteenth, of galls to the cochineal, gives it greater stability, but this permanency is gained at the expence of its lustre. The fine crimson disappears, and the colour approaches more to the red or middle hue. An advantage attending the use of cochineal, is its little effect on the white or unprinted part of the cloth, which acquires no stain in the dyeing, but what is completely removed by simple washing, or, in some particular cases, by very gentle branning. From two to three ounces of cochineal, according to the fulness of the pattern, are sufficient for a piece of light ground. The pale delicate crimson grounds, with white objects, require from four to five ounces. It must be finely ground, and inclosed in a linen or cotton bag, suspended in the dye-copper, from whence it can be occasionally taken and squeezed or wrung, for the more complete extraction of the colour.

In dyeing with cochineal, the value of this drug renders every precaution for economizing its use indispensably necessary, and a considerable saving is made by diminishing as much as possible the quantity of the dye liquor. It is well known, that colouring matter of any kind, held in solution in the dye-copper, can only be exhausted to a certain degree, even by fresh and undyed goods; there is a certain point at which the affinity of the water for colouring matter becomes equal to that of the strongest mordants, and all that is thus retained may be considered as totally lost, except when fresh portions of colouring matter are added to the already exhausted liquor, and the operation of dyeing again renewed, in which case the loss is inversely as the number of successive operations performed in the same liquor. In dyeing with cochineal, therefore, no more water should be used than is barely sufficient to cover the goods when pressed down close into the copper, with a stick as they come over the winch, and three successive dyeings, at least, should be passed through the same liquor before it is let off, and the copper replenished with fresh water. Long continued heat has a tendency to injure the cochineal crimson, and incline it too much to the purple hue; each dyeing, therefore, should be withdrawn shortly after it has attained the boiling point. The first sets may be boiled three minutes; the second, one; the third set may be kept five or six minutes at the boil, if it consists of darker colours, such as chocolates, dark purples, &c.; but if crimsons, the colour, without boiling, will incline very much to the purple hue, and be much inferior to the first, and even to the second sets. On this account it is proper, when the work will admit of it, to dye the pale crimson grounds first, follow after with the stronger light grounds, and, lastly, with the darker colours above-mentioned.

The use of tin vessels in dyeing scarlet or woollen, (where the acid solutions used in that operation render them indispensably necessary) has induced many calico printers to employ them in dyeing cotton, where no acid solution is present, and where the good effects of tin may be supposed not to apply. It is certain, however, that the hue of the pale and delicate crimson grounds produced in a tin vessel is much superior to that produced in copper, and the cause of this difference is satisfactorily explained by the experiments of Mr. Thomson. From these experiments, which will be more fully detailed in another part of this work, it appears that the colouring matter of cochineal possesses very distinct acid properties.

Turnings of pure soft iron digested in a strong decoction of cochineal were dissolved, with disengagement of hydrogen gas. The solution, at first purple, gradually acquired a more intense colour, approaching to black. Exposed to the atmosphere, it gradually absorbed oxigen, and let fall a black precipitate. It communicated to cloth a dark grey or purple colour, which was not removed by washing. With tin the decoction of cochineal formed a beautiful crimson solution, and, with copper, a dull crimson inclining to purple; both these solutions imparted their colour to cloth, which rinsing did not remove. Hence it appears that the difference in the colours, produced in a tin and in a copper vessel, arise from the action of the colouring matter on the substance of the vessel itself.

The colouring matter of cochineal also acts powerfully on the earths and metallic oxides, or on its own combinations with them or cloth. A piece of calico impregnated with a weak aluminous mordant, and dyed in a strong decoction of cochineal, takes at first a dye which is, however, speedily removed, and the mordant itself soon after carried off the cloth. The same takes place with the dilute solutions of iron. In dyeing with cochineal, therefore, in the way prescribed above, some care is necessary in the management of those goods, on which weak as well as strong mordants are applied, lest with the treatment necessary to bring up the latter to their proper strength and fulness, the former be totally destroyed.

The beautiful pigment carmine, used chiefly in miniature and

and water-colour painting, and fometimes under the name of rouge, to frefhen the cheeks of pallid or faded beauty, is alfo a preparation of cochineal. It is a light, foft, velvety powder, of a moft rich and magnificent fcarlet, inclining a little to crimfon. It was formerly made from kermes, whence its prefent name is derived.

The preparation of carmine, notwithftanding the numerous proceffes detailed in various works, ftill remains one of thofe fecrets which are confined to the laboratories of a few. Its conftitution, indeed, and the general nature of the procefs for obtaining it, are well known; but excellence in colours of this kind often depending on particular hue, arifing from minute but important conditions in the preparation, approved proceffes are guarded with religious care, confined to the workfhops that gave them birth, in which myftery and prejudice are defpotic.

We fubjoin the following formula without vouching for its merit; it is, however, at leaft, as good as any other publifhed.

Pour two quarts of fine clear river water into a clean copper pan, and, when boiling, add two ounces of the beft grain cochineal, finely ground and fifted. Boil fix minutes, ftirring carefully the whole time. Add fixty grains of fine Roman alum in powder, and boil three minutes longer, after which withdraw it from the fire and let it cool a little. Decant off the liquor carefully from the grounds, and ftrain through a filk fieve fine enough to retain the undiffolved grains. Pour it into well-glazed porcelain difhes and fuffer it to remain undifturbed three or four days, after which time again decant the red liquor into other difhes from off the fediment which has formed, and which, dried in the fhade and free from duft, forms the fine carmine. Another depofition takes place at the end of a few days from the decanted liquor, which forms a good carmine of fecond quality, and there ftill remains colouring matter fufficient in the remaining liquor to afford a rich lake.

The following procefs, not very different from the former, has been recommended; and, if carefully purfued, will yield a pigment greatly fuperior to the carmine that is generally met with. Into a fourteen-gallon boiler of well-tinned copper put ten gallons of diftilled or very clear rain water (fpring water will not anfwer the purpofe). When the water boils, fprinkle in, by degrees, a pound of fine cochineal, previoufly ground in a clean ftone mortar to a moderately fine powder; keep up a gentle ebullition for about half an hour, and then add three ounces and a half of cryftallized carbonat of foda; in a minute or two afterwards draw the fire, and then add to the liquor an ounce and a half of Roman alum, very finely pulverized; ftir the mafs with a clean ftick till the alum is diffolved, then leave it to fettle for 25 minutes, and afterwards draw off the clear liquor with a glafs fyphon, and feparate the reft of the fluid from the fediment by ftraining it through a clofe linen cloth. Replace the clear liquor in the boiler, and ftir in the whites of two eggs, previoufly well beaten with a quart of warm water; then light the fire again and heat the liquor till it begins to boil, at which time the albumen of the eggs will coagulate and combine with the earth of the alum and the fineft part of the colouring matter; this fediment is the *carmine*, and being feparated by filtration, and well wafhed on the filter with diftilled water, it is to be fpread very thin on an earthen plate, and flowly dried in a ftove, after which it is fit for ufe. The fineft part of the colouring matter of the cochineal being thus feparated, the refidue may be employed in the preparation of *red lake* in the following manner: Add two pounds of pearlafh to the red liquor from which the carmine was precipitated, and return it into the boiler together with the dregs of the cochineal, and boil the whole gently for about half an hour; then draw the fire, and, after the fediment has fubfided, drain off all the clear liquor into clean earthenware veffels. Then pour upon the fediment a fecond alkaline ley, prepared by diffolving a pound of pearlafh in two gallons of water, and boil this alfo upon the dregs for half an hour; by which procefs the whole of the colouring matter will be exhaufted. Separate by filtration the liquor from the dregs, and return both the alkaline folutions into the copper. When this bath is as hot as the hand can bear, add, by degrees, three pounds of finely pulverized Roman alum, obferving not to add a fecond portion till the effervefcence from the firft has entirely fubfided. When the whole of the alum has been put in, raife the fire till the liquor fimmers, and continue it at this temperature for about five minutes, at which time, if a little is taken out and put into a wine glafs, it will be found to confift of a coloured fediment diffufed through a clear liquor; after ftanding quiet a while the greater part of the clear fupernatant liquor may be poured off, and the refidue being placed on the filter, will there depofit the coloured lake, which, after being accurately wafhed with clear rain water, may be covered with a cloth, and allowed to remain for a few days till it is half dry: it is now to be feparated from the filter, to be made up in fmall lumps, and placed in a ftove to dry. By this management a pound of good Mexican cochineal will afford one ounce and a half of carmine, and about a pound and a quarter of red lake.

If the colour is required to incline fomewhat towards fcarlet, this may be effected by grinding along with the cochineal from a quarter to half an ounce of the beft annotto.

The French add to the infufion of cochineal a fmall proportion of *autour*, a bark containing yellow colouring matter, and alfo of *chouan*, a greenifh yellow feed, both from the Levant. They ferve to brighten the hue of the carmine, and incline it more to fcarlet. Carmine has a flight tafte, eafily recognized as that of cochineal. It is fparingly foluble in water, to which it communicates its own colour. Mixed up with water it works ftiffly with the pencil and affords a poor colour. Ammonia diffolves it inftantly, forming with it a deep tranfparent crimfon-coloured folution, inclining much to purple. This is the teft of its purity, for the inferior or adulterated carmine is infoluble, and falls to the bottom. The painters generally grind or mix it with ammonia for the deep rich reds, and its folutions in that alkali afford moft beautiful pink or rofe colours.

Carmine appears to be a lake in which the colouring principle predominates very much over the bafis; hence its folubility in ammonia, which the true or perfect lakes do not poffefs.

COCHINO, in *Geography*, a town of European Turkey, in the ifland of Lemnos. N. lat. 39° 57′. E. long. 25° 22′.

COCHITOTOL, in *Ornithology*, the name given by Fernandez to the bird fuppofed by Buffon to be the female orange promerops, the *promerops barbadenfis* of Briffon, the *avis paradifiaca Americana elegantiffima* of Seba, and a variety of the *upupa aurantia* of Gmelin. See UPUPA.

COCHLEA, in *Anatomy*, a part of the labyrinth of the ear, which refembles a fnail fhell. See EAR.

COCHLEA, in *Conchology*, an obfolete term, often applied by old writers to univalve fhells of the fpiral kind, and thofe chiefly of the nerita and helix genera, and fometimes the trochi, and even turbo.

COCHLEA is alfo a fpecies of MADREPORA, which fee.

COCHLEA, in *Mechanics*, one of the five mechanical powers; otherwife called the SCREW, which fee.

It is thus denominated, from the refemblance a fcrew bears to the fpiral fhell of a fnail, which the Latins call *cochlea*.

COCHLEARIA,

COCHLEARIA, in *Botany*, (so called from the form of the leaves, which, being slightly hollowed, resemble an old-fashioned spoon.) Linn. Gen. 803. Schreb. 1079. Willd. 1228. Juss. 240. Vent. 3. 109. Tourn. 101. (Cranson; Encyc.) Class and order, *tetradynamia siliculosa*. Nat. Ord. *Siliquosæ*, Linn. *Cruciferæ*, Juss. Vent.

Gen. Ch. *Cal.* Four-leaved; leaves egg-shaped, concave, open, caducous. *Cor.* Petals four, equal, egg shaped, twice the size of the calyx, open. *Stam.* six, awl-shaped, the length of the calyx; anthers obtuse, compressed. *Pist.* Germ superior, heart-shaped, or oval; style very short, permanent; stigma obtuse. *Peric.* Silicle heart-shaped, gibbous, turgid, somewhat emarginate, tipped with the permanent style, rugged, two-celled.

Ess. Ch. Silicle gibbous, rugged; valves gibbous, obtuse. Seeds several.

Sp. 1. C. *officinalis.* Linn. Sp. Pl. 1. Mart. 1. Lam. 1. Willd. 1. Flor. Dan. tab. 135. Lam. Ill. tab. 558. fig. 1. Woodv. Med. Bot. tab. 29. Eng. Bot. 551. (C. folio subrotundo; Bauh. Pin. Tourn. 215. C. batava; Lob. Ic. 293. Nasturtium; Hall. Helv. n. 503.) Common scurvy-grass. "Root-leaves roundish: stem ones oblong, somewhat sinuated; fruit globular." β. Minor rotundifolia nostras; Rai. Syn. 303. γ. C. groenlandica; With. not Linn. C. rotundifolia; Dill. in Rai. Syn. 302. *Root* annual or biennial, white, rather thick, elongated, with hairy fibres; whole herb smooth, somewhat fleshy, very various in size. *Stems* angular, branched in a corymbose manner; leafy. *Root-leaves* on long petioles, roundish, kidney-shaped, somewhat toothed or repand; stem-leaves alternate, sessile, embracing the stem, angular or sinuated. *Flowers* white, in terminal corymbs, which are afterwards lengthened into racemes; bractes none; calyx obtuse, spreading, concave; petals inversely egg-shaped, entire. *Silicles* globular, not emarginate, but little rugged, slightly veined, crowned with a short style. *Seeds,* five or six in each cell. Common on the sea-coasts of Europe, and not unfrequent in mountainous countries, far inland. On mountains it is generally smaller; but in the rocky wood above Bolton Abbey, in Craven, Yorkshire, eighty miles from the sea, it grows as luxuriantly as on the coast. It has a warm, acrid, bitter taste; and a pungent, rather unpleasant, smell when bruised. Its active matter is extracted by maceration, both in water and spirits; but its principal virtue resides in an essential oil, separable in a very small quantity, by distillation in water. It has long been considered as the most effectual of all the antiscorbutic plants; and is, therefore, most liberally provided by the benevolent author of nature, on the coasts of high latitudes, where the scurvy is most prevalent. Foster found it also in great abundance in the islands of the South sea. A remarkably volatile and pungent spirit, known by the name of *spiritus antiscorbuticus, sive mixtura simplex antiscorbutica dranizii,* is prepared from it, which has been found an useful remedy in paralytic affections, and other diseases that require an active stimulus. But as an antiscorbutic, the expressed juice, or the plant itself, eaten in a salad with water-cresses and brook-lime, is the most beneficial. 2. C. *anglica.* Linn. Sp. Pl. 2. Mart. 3. Lam. 3. Flor. Dan. tab. 329. Eng. Bot. tab. 552. (C. folio sinuato; Bauh. Pin. 110. Tourn. 215. Rai. Syn. 303. C. britannica; Dod. Pempt. 594. Ger. Amen. 401.) English scurvy-grass. "Root-leaves egg-shaped, entire; stem-leaves lanceolate, toothed; silicles elliptical, reticularly veined." *Root* annual or biennial. *Herb* smooth, somewhat fleshy, variable in the form and size of its leaves, generally smaller than the preceding. *Root-leaves* on long petioles, rarely a little toothed or repand; stem ones embracing the stem, scarcely sinuated. Flowers like those of C. officinalis. *Silicle* twice the size, turgid, sometimes almost globular, crowned with a longish style. A native of England on muddy sea-shores. 3. C. *danica.* Linn. Sp. Pl. 4. Mart. 2. Lam. 2. Flor. Dan. 190. Eng. Bot. 696. (C. aremorica; Tourn. 215. Barrel. icon. 1205. fig. 1. C. repens et minor erecta; Bauh. Pin. 53. Thlaspi hederaceum; J. Bauh. 2. p. 933. Lob. ic. 615.) "Leaves all deltoid, and petioled; silicles elliptical, reticularly veined." *Root* annual or biennial, smaller than either of the preceding. *Stems* about five inches long, several, seldom branched, partly decumbent, striated, reddish, smooth. *Leaves* nearly equal in size, uniform, three or rarely five-lobed, somewhat toothed, resembling those of ivy. *Flowers* white, small, in rather short corymbs. *Silicle* quite elliptical, less turgid, crowned with a shorter style. *Seeds* about six in each cell. A native of the sea coasts of Denmark and Sweden. In England less common. First discovered by Lawson in Walney island, Lancashire, afterwards by Llwyd in Anglesea, and is probably to be found in other parts of the western coast. We have observed it abundantly at Blackpool. Mr. Crowe detected it in salt marshes at Wells in Norfolk, and Mr. D. Turner, and Mr. Sowerby in several parts of the southern coast, from Portland island to the Land's End. 4. C. *groenlandica.* Linn. Sp. Pl. 4. Mart. 4. Lam. 4. Willd. 4. "Leaves kidney-shaped, fleshy, quite entire." *Root-leaves* very small, convex underneath, veinless, on long petioles. 5. C. *sibirica.* Willd. 5. "Leaves heart-shaped, gash-toothed." *Stem* erect, a foot high, simple striated, smooth. *Leaves* alternate, on long petioles, obtuse, four lines long, and as many broad, deeply toothed; teeth obtuse; upper petioles the length of the leaves; lower ones four times as long. *Flowers* white, in racemes. *Silicles* small, lanceolate, one or two seeded. A native of Siberia. 6. C. *acaulis.* Willd. 6. Desfont. Atl. 2. p. 69. "Stemless; leaves cordate-kidney shaped; scapes filiform, one-flowered, quite simple." Whole plant scarcely half an inch high, growing in tufts, smooth. *Leaves* small, petioled, somewhat fleshy, smooth. *Scapes* about the length of the leaves. *Flowers* blue or white, the size of those of C. officinalis: border of the petals entire, inversely egg-shaped. *Silicle* inflated, thick, oblong, many-seeded; style very short. A native of Portugal and Morocco. 7. C. *saxatilis.* Lam. 6. (Myagrum saxatile; Linn. Sp. Pl. Mart. Willd. Thlaspi alpinum majus et minus; Bauh. Pin. 107. T. alpinum myagroides; Pon. Bald. 185. Clus. Hist. 338. Alyssum; Hall. Helv. n. 490. Allion. ped. n. 887.) "Lower leaves petioled, ovate-oblong, slightly serrated; upper ones nearly sessile, tongue-shaped; silicle globular." Lam. *Root* perennial. *Stem* six or seven inches high, very slender, weak, smooth, reddish at its base, branched near the top. *Root-leaves* spreading on the ground. A native of rocky ground on the southern coast of France, and on the mountains of Switzerland and Italy. 8. C. *auriculata.* Lam. 7. "Leaves oblong, arrow-shaped at the base, auricled, embracing the stem; racemes long, loose, simple." Entirely smooth. *Stem* six or seven inches high, branched at the base, slender, weak. *Leaves* larger than those of C. saxatilis; root-leaves spatula-shaped, entire, narrowed into petioles; stem ones oblong, generally obtuse, enlarged and furnished with some angular teeth near the summit, embracing the stem; arrow-shaped and auricled at the base. *Flowers* white. *Silicles* oval-globular, crowned with the very short style. Found by La Marck on uncultivated ground in Auvergne. 9. C. *draba.* Linn. Sp. Pl. 8. Mart. 8. Lam. 8. Willd. 11. Jacq. Aust. 4. tab. 315. (Lepidium humile, incanum arvense; Tourn. 216. Draba umbellata, sive major capitulis donata; Bauh. Pin. Morif. Hist. 2. tab. 21. fig. 1. bad. Arabis sive draba et nasturtium babylonicum; Lob. ic. 224.) "Leaves lanceolate, embracing the stem, toothed." *Root* perennial, striking deep. *Stems* several, about a foot high, striated, leafy,

leafy, almoſt ſimple, annual. *Leaves* diſtantly toothed, ſlightly pubeſcent on both ſides, pale green or hoary, with two acute auricles at the baſe. *Flowers* white, ſmall, in ſeveral ſhort racemes, which form a terminal panicled corymb. *Silicle* inflated, heart-ſhaped, ſmooth, with a ſingle ſeed in each cell. A native of Italy, Auſtria, and the ſouth of France. 10. C. *glaſtifolia*. Linn. Sp. Pl. 7. Mart. 7. Lam. 9. Willd. 10. (C. altiſſima, glaſtifolio; Tourn. 215. Lepidium glaſtifolium; Bauh. Pin. Moriſ. Hiſt. 2. tab. 2. fig. 5.) "Stem-leaves cordate-arrow-ſhaped, embracing the ſtem." The habit of a turritis. *Root* biennial. *Stem* from three to five feet high, erect, leafy, cylindrical, ſmooth, with a few ſhort branches. *Lower leaves* oblong, narrowed into a petiole. *Flowers* white, ſmall; in ſhort, alternate racemes, which form an elongated terminal panicle. *Silicles* globular. *Seeds* numerous. A native of Germany, about Ratiſbon. The whole plant is eſteemed deterſive, diuretic, lithontriptic, and antiſcorbutic. 11. C. *armoracia*. Linn. Sp. Pl. 6. Mart. 6. Lam. 10. Willd. 8. Woodv. Med. Bot. tab. 150. (C. folio cubitali; Tourn. 215. Raphanus ruſticanus; Bauh. Pin. 96.) Horſe radiſh. "Root-leaves oblong, crenate; ſtem ones lanceolate, gaſhed or entire." Dr. Smith. *Root* perennial, ſpindle-ſhaped, long, very durable, acrid. *Stems* about two feet high, erect, corymbous, leafy. *Root-leaves* petioled, very large, ſometimes pinnatifid, veined; ſtem ones ſeſſile. *Flowers* white. *Silicle* elliptical, with a very ſhort ſtyle and ſhort ſtigma. *Fruit* often abortive. A native of England and other parts of Europe, in moiſt ground, and on the banks of rivulets. The uſe of its ſcraped root in warm pickles, and as a poignant condiment to various kinds of animal food, is well known. It has alſo acquired much reputation as a medicine, and is a powerful ſtimulant, whether externally or internally employed. *Externally* it readily inflames the ſkin, and if its application be long continued, produces bliſters. In this reſpect it is uſed with advantage in caſes of palſy and rheumatiſm. One dram of the root infuſed in a cloſe veſſel with four ounces of water for two hours, and made into a ſyrup with double its weight of ſugar, taken *internally*, in the quantity of a teaſpoonful or two, and ſwallowed leiſurely, or at leaſt two or three times repeated, has been found to be ſuddenly effectual in relieving that kind of hoarſeneſs which proceeds from an interrupted ſecretion of mucus. Infuſed in water, and taken into the ſtomach, it proves ſtimulant to the nervous ſyſtem, and is on that account uſeful in palſy and chronic rheumatiſm, whether ariſing from ſcurvy or other cauſes. This infuſion, taken with a large draught of warm water, is a ready emetic, either by itſelf, or to aſſiſt the operation of other emetics. The root cut, without bruiſing, into very ſmall pieces, and ſwallowed without chewing, may be taken to the quantity of a table-ſpoonful; and, according to Bergius, has been found very uſeful in arthritic caſes; which, however, Dr. Cullen ſuppoſes to have been of the rheumatic kind. Its matter, like that of other ſiliquoſe plants, paſſes readily to the kidneys, and thus proving a powerful diuretic, is uſeful in dropſy, by promoting both urine and perſpiration. It has alſo long been known as an active antiſcorbutic. It is extremely pungent both to the taſte and ſmell, but nevertheleſs contains a ſecret juice, which ſometimes exudes in little drops upon the ſurface. Its pungent matter is very volatile, being totally diſſipated in drying, and carried off in evaporation or diſtillation by water and rectified ſpirit. It impregnates both water and ſpirit, by infuſion or diſtillation, very richly, with its active matter. In diſtillation with water, it alſo yields a ſmall quantity of eſſential oil, exceedingly penetrating and pungent. See Cullen's Materia Medica, vol. ii. p. 169.; and Woodville's Medical Botany, vol. iii. p. 407. An infuſion of it in cold milk is ſaid, by Dr. Withering, to be one of the ſafeſt and beſt coſmetics. 12. C. *macrocarpa*, Willd. 9. Waldſtein and Kitabel, pl. Hung. "Root-leaves cordate-egg-ſhaped, crenate; ſtem ones lanceolate, cartilaginouſly toothed; ſilicles elliptical, inflated." Nearly allied to the preceding ſpecies. A native of Hungary in moiſt ground.

COCHLEARIA *coronopus*, Linn. &c. See CORONOPUS *ruelii*.

COCHLEARIA, in *Gardening*, comprehends a plant of the top-rooted eſculent kind, the horſe-radiſh (C. *armoracia*) which has a creeping perennial root, the leaves very large, varying much, the flowering ſtem a foot or eighteen inches in height, and the flowers white, in looſe panicles, appearing in May.

Method of Culture. In the culture of this plant there is little difficulty, as it is readily effected by planting ſuch cuttings of the roots as contain buds or eyes. Thoſe made from the tops, and which have the heads or crowns of the plants to them, are the beſt. The off-ſets and ſide-ſhoots may likewiſe be employed for the purpoſe, as is moſtly the caſe with market-gardeners. They ſhould be about an inch or two in length. As theſe plants require to be put into the ground to a great depth, in order that they may form long fine roots, the earth ſhould either be dug over before the cuttings are placed in, or trenched to the depth of fifteen or twenty inches at the time, according to the method of planting that is made uſe of, and in either mode the ground be well looſened, and broken down fully to the above depth.

The ſorts of ground moſt adapted to the growth of theſe roots are thoſe of the more light deep kinds; but they will ſucceed tolerably on almoſt any. When the land has been trenched over in the above manner, the uſual mode of planting is by means of the dibble; but there is another practice which is ſometimes followed, which is that of trenching in the ſets, or placing them in the earth at the time it is dug over to the full depth of the looſened mould.

But in the firſt method, after the ground has been prepared, a line is ſtretched acroſs, beginning at the end, and holes made to the depth of fifteen or twenty inches along it, by means of a long ſharp iron dibble, at the diſtance of nine inches from each other, a ſet or cutting being dropped into each hole, and the mould cloſed upon it. The line ſhould then be moved forward to the diſtance of twenty inches or two feet, and another row put in in the ſame manner, proceeding in the ſame way till the whole of the ground is planted over.

In performing the work in the latter mode, the ground ſhould be made light and looſe, beginning at one end of the piece, and opening a trench two ſpades wide, and one ſpade deep, digging the bottom; then a row of cuttings ſhould be ſet along the middle of the bottom nine inches diſtant, inſerting them to their tops in the earth; then digging the next trench the ſame width and depth, turning the earth into the firſt upon the row of plants, breaking all large clods, and levelling the top. After this, proceed to the ſecond trench, planting it in the ſame way, performing the whole of the work in a ſimilar manner, and then levelling the ſurface by the rake.

The moſt proper ſeaſon, or time of the year for this work, is in the autumn for the dryer ſorts of land, and in the early ſpring, as in February, or beginning of the following month, for ſuch as are of a moiſt quality.

In theſe methods of planting, in order that no time may be loſt, the ground may be ſown the firſt year with ſpinach, radiſhes, or any ſlight-rooting crop, that comes off early in the ſummer, to allow of the plants being kept clean afterwards by hoeing; which is all the culture they require in bringing the roots to a proper ſize for uſe.

Sometimes it is the caſe, eſpecially where the land is ſuitable for them, that the plants make ſuch progreſs as to have roots large

large enough for uſe in the courſe of a few months; but if not much wanted, they are better to remain a twelvemonth, or two or three years, as by ſuch delay they are much larger and finer.

In reſpect to taking up the roots for uſe, the beſt method is to open a trench two ſpades wide, cloſe on the ſide of the firſt row of plants, and fully as deep as the ſtool or bottom of the roots, without diſturbing them; then with a large knife or ſharp ſpade to cut off all the ſhoots, large and ſmall, of each ſtool cloſe and level, from whence they riſe, leaving the old or parent ſtools in the earth; and after having taken up all the plants of the firſt trench, proceeding to the next row in the ſame manner, turning the earth of it into the firſt, and cutting off all the ſhoots as before, taking up the whole in the ſame way as wanted. By this means the remaining undiſturbed ſtools continue to ſend up a freſh ſupply of ſhoots in ſucceſſion for many years; but after the two firſt years the ſtools begin to ſpread at bottom, and ſend up many ſmall ſhoots between and in the rows; all of which intervening ſmall ſpawn ſhould be annually drawn up in the beginning of ſummer, to render the principal ſhoots large and fine. And though the ſtools of theſe roots endure many years, in time they become weak or worn out, as well as the ſoil; conſequently, in ſix or ſeven years, when the ſhoots become weak and ſmall, a freſh plantation ſhould be made in ſome other place. In order to have fine roots it is better, however, to do it every three or four years.

Theſe roots are much uſed for culinary purpoſes when ſcraped very fine, eſpecially for fiſh, and ſome other ſorts of food.

Whenever more of the roots are taken up at a time than are wanted, they may be preſerved in their juicy ſtate for ſome time, by putting them in a little dry ſand.

Cochlearia, in *Ancient Geography*, a place in the iſland of Sardinia, between Uſſia and Portus Luquidonis, according to the Itinerary of Antonine.

Cochlearia, in *Ornithology*, a ſpecies of *Cancroma*, which ſee.

COCHLITES, in *Natural Hiſtory*, a term comprehending ſeveral kinds of foſſil ſhells, found lodged in the Britiſh ſtrata, and reſembling ſnails and periwinkles.

COCHLIUSA, an iſland of Aſia Minor in the Mediterranean ſea, ſituated on the coaſt of Lycia.

COCHRYNNA, a river of Thrace, in the environs of the Chalcidic territory.

COCINTUM, a town of Italy in Brutium, near the eaſtern coaſt, at a ſmall diſtance to the weſt of the promontory of the ſame name.

COCK, Matthew, and Jerome, in *Biography*, two brothers, painters of Antwerp, who flouriſhed about 1551. Matthew is ſaid by Van Mander, to have been one of the firſt artiſts amongſt the Flemings, who painted landſcape in a good ſtyle. However, his pictures, though finiſhed, are hard, and much reſemble thoſe of old Breugel.

Jerome, his brother, though poſſeſſed of no ſmall ſhare of ability, gave himſelf up to engraving, and publiſhing many excellent prints, though in the old dry manner, after the works of Matthew Cock, old Breugel, and Francis Florio, as well as from the pictures of the beſt maſters of Italy, where he long reſided; beſides which, he gave to the world many intereſting collections of antiquities, topography, &c. He died in 1570, many years after the death of Matthew his brother. Baldinucci. Heinecken.

Cock, *of a Muſket*, in *Gunnery*, the part of the lock which ſuſtains the two ſmall pieces of iron called jaws, between which the flint is fixed.

To cock a muſket, piſtol, &c. is to fix the cock in ſuch a manner as to have it ready for an inſtant diſcharge.

Cock, in *Ichthyology*, a ſmall fiſh that is ſometimes very common on the ſhore of Cornwall; the *labrus coquus* of Gmelin, purple, and obſcurely cæruleous, yellow underneath, with a rounded tail.

Cock, *Phaſianus gallus* of Linnæus, in *Ornithology*, the name of the male of gallinaceous birds: the ſpecific character of which is, that it has a compreſſed caruncle on its top, and a double one on its cheek; that its ears are naked, and that its tail is compreſſed and riſing. For the hiſtory and varieties of this bird, ſee Phasianus *Gallus*. For its uſes in domeſtic economy, ſee Eggs, Hatching, Hen, and Poultry.

In the choice of a *dunghill cock*, he ſhould be of a large body, very long from the head to the rump, thick in the girth, the neck long, looſe, and high; the comb, wattles, and throat large; the eyes round and large, and anſwerable to the colour of his plume or main, as grey with grey, yellow with yellow, and ſo of the reſt; his beak ſhould be ſtrong and hooked; and his main or neck-feathers very long and gloſſy, covering his neck and ſhoulders; the legs ſhould be ſtrait, and of a long beam, with very large and long ſpurs, a little bending; the colour ſhould be black, yellow, or browniſh; the claws ſhould be long and ſtrong; the tail long, bending back, and covering the whole body; the wings very ſtrong; and the general colour ſhould be reddiſh. The cock is a heavy bird, and his gait is compoſed and ſlow. His wings are very ſhort, and hence he ſeldom flies, and the violence of his efforts is ſometimes indicated by his ſcreams. He crows either in the night or day, but not regularly at certain hours, and his note is very different from that of the female. He ſcrapes the ground to ſeek his food, and ſwallows, with the grains, ſmall pebbles, which ſerve to aſſiſt digeſtion. He drinks, by taking a little water into his bill, and raiſing his head at each draught. He moſt frequently ſleeps with one foot in the air, and his head covered by the wing on the ſame ſide. The thigh on which the body reſts is commonly more fleſhy than the other; and it is ſaid that our epicures well know how to diſtinguiſh them. In its natural ſituation, the body is nearly parallel to the ground, as is alſo the bill; the neck riſes vertically, the forehead is ornamented with a red fleſhy comb, and the under part with a double pendant of the ſame colour, which, ſays Buffon, is neither fleſh nor membrane, but of a peculiar nature, different from every thing elſe. In both ſexes the noſtrils are ſituated on either ſide of the upper mandible, and the ears on either ſide of the head, and below each ear is ſpread a white piece of ſkin. The feet have commonly four toes, ſometimes five, but always three of them placed behind. The feathers riſe by pairs from each ſhaft. The tail is nearly ſtraight, but admits of a ſmall elevation and depreſſion. The male is diſtinguiſhed by having the two feathers in the middle of the tail much longer than the reſt and bent into an arch; the feathers of the tail and rump are alſo long and narrow, and the feet are armed with ſpurs. A good cock has eyes ſparkling with fire, boldneſs in his demeanour, and freedom in his motions, and diſplays force in all his proportions. He is ſo ſingularly ſalacious, that though he ought not to be allowed more than 12 or 15 hens (Columella recommends, indeed, that they ſhould not exceed five); yet if he had 50 a day, he would not, it is ſaid by Aldrovandus, neglect one of them. However, in this caſe it is not certain that he would fecundate the eggs of the female. Ardent in his paſſion, the firſt thing he does after he is diſcharged from his rooſt in the morning is to tread his hens; and if he is for ſome time deprived of his family, he makes his addreſſes to the firſt female he meets, though of a very different ſpecies, and even courts the firſt male that occurs. The firſt fact is mentioned by Ariſtotle; the ſecond is proved by by an obſervation of Edwards, and may be inferred from a law mentioned by Plutarch, in his treatiſe on the queſtion "Whether brutes reaſon," which enacted, that a cock convicted of this unnatural act, ſhould be burnt alive. The cock is extremely watchful of his females, and manifeſts great inquietude and anxiety; he hardly ever loſes ſight of them; he leads and defends them, and threatens them with his menaces; he collects them together when they ſtraggle, and never eats till he has the pleaſure of ſeeing them feeding around him. The different inflexions of his voice, accompanied by various ſignificant geſtures, are a kind of language that ſerves to communicate his ſentiments. When he loſes them he expreſſes grief. Although he is no leſs jealous than amorous, he does not abuſe his wives, but directs his rage againſt his rivals. Large as is his family, it is obſerved that he has a favourite female to whom he manifeſts peculiar attention. It was known as long ago as the time of Ariſtotle, (vid. de partibus animalium, lib. iv. 5.) that the cock had organs of generation concealed within his body. The bulk of theſe varies in different ſpecies, and in different animals of the ſame ſpecies, at different times; but whatever be their ſize, they are very important in the animal economy, as is evinced by the fecundation of eggs, and the wonderful changes reſulting from their extirpation. This operation is commonly performed when the bird is three or four months old. After emaſculation it grows plumper, and its fleſh becomes more juicy and delicate, and when ſubjected to a chemical analyſis, yields different products from thoſe which it would have afforded before caſtration. The extract of the lean of a capon is ſomewhat leſs than the 40th part of its total weight; whereas it amounts to 1-12th in a pullet, and rather more than 1-7th in a cock. Beſides, the extract of cock's fleſh is very dry, while it is difficult to ſeparate the humidity from that of a capon (Mem. Acad. Roy. Scienc. an. 1730, p. 231.) The capon is no longer liable to moult; his note is altered, his voice broken and ſeldom heard; he is treated roughly by the cocks, with diſdain by the females; and deprived of all the appetites which he naturally poſſeſſed, he is not only excluded from the ſociety of his equals, but extruded, as it were, from his ſpecies. To eat, ſleep, and fatten, are in this ſtate its principal objects. However, he may even now be taught to rear and tend young chickens. For this purpoſe the capon muſt be kept ſome days in a dark place, only bringing it out at regular hours to feed, and accuſtoming it gradually to the ſight and company of a few ſtout chickens; for theſe it will ſoon acquire a fondneſs, and will lead them with as much affection and aſſiduity as their mother. It will conduct even a greater number than a hen; for its wings ſpread and afford more ſpacious ſhelter; and the hen, freed from its ſolicitude and toil, will ſoon begin again to lay.

Some have practiſed another method of teaching a capon to clutch a brood of chickens, more cruel, but no leſs effectual than the former; which is that of rendering him very tame ſo as to feed from one's hand: and then, about evening, plucking the feathers off his breaſt, and rubbing the bare ſkin with nettles; the chickens are then put to him, and preſently run under his breaſt and belly, and probably by rubbing his bare ſkin gently with their heads, allay the pain which the ſtinging of the nettles had occaſioned. This is repeated for two or three nights, till the capon contracts an affection for the chickens, which have given him relief, and takes them under his protection. A capon accuſtomed to this ſervice will repeat it to one brood after another.

Thus the capon, though condemned to ſterility, will ſtill contribute indirectly to the preſervation and multiplication of its ſpecies. Another operation performed on the cock is, after cutting the comb as uſual, to ſubſtitute in its ſtead one of the young ſpurs which has juſt begun to ſhoot; thus engrafted, it gradually ſtrikes root into the fleſh, thence extracts its nouriſhment, and often grows more luxuriantly than it would have done in its natural ſituation.

Chickens are not hatched with that creſt, and thoſe reddiſh membranes which diſtinguiſh them from other birds. Theſe parts do not begin to unfold themſelves for the firſt month, after they have left the ſhell; at two months the young cocks crow, and fight with one another; but it is commonly after an interval of five or ſix months that they manifeſt any paſſion for the hens, and that theſe begin to lay. In both ſexes the complete time of their growth is a year or 15 months. This period of their growth would imply that the ordinary extent of their life does not exceed ſeven or eight years, if the ſame proportion ſubſiſted in birds as in quadrupeds. But this has been obſerved to be much longer. Some have limited their age to 10 years; others have extended it in their domeſtic condition to 20 years; and in a ſtate of abſolute liberty to 30 years. But as cocks and hens are bred for profit, the hens and capons that are deſtined for the table, ſeldom enjoy above one year's exiſtence, and moſt of them have only one ſeaſon. Thoſe which are ſelected for the multiplication of the ſpecies become ſoon exhauſted, and none are permitted to arrive at their natural period; ſo that cocks are ſeldom or never known to die of age.

Cock, *of the Game*, or *Game Cock*, *Phaſianus gallus*, of Linnæus: *Phaſianus gallinaceus* of Ray, Willughby, and other ornithologiſts.

The Engliſh game-cock is vulgarly imagined to be the offspring of the domeſticated fowl and the pheaſant: this idea is, however, not at all aſſented to by ornithologiſts, or the amateurs of the art of cocking. On more ſure grounds its origin is referred to the wild cock of India, found not unfrequently on the continent of India, and the iſles St. Jago, Pulocondore, Timor, Philippine and Molucca iſlands, Sumatra, Java, New Guinea, Tinian, and the iſles of the South Seas. At Sumatra and Java they are noticed as being particularly large. Latham has obſerved that they breed moſt freely in warmer ſituations; in very cold regions, though they live and thrive, they ceaſe to multiply.

According to Mr. Pegge, in the "Archæologia," vol. iii. No. 19, the art of cock-fighting is referred to the Greeks.

Jacobus Palmerius, a writer cited by Mr. Pegge, pretends that the traces of this diverſion may be diſcovered among the barbarians of Aſia, as early as the reign of Crœſus, king of Lydia, A. M. 3426, and 558 years before Chriſt. But the learned antiquary apprehends, that the fact to which this writer refers, furniſhes no evidence that quails, uſed among the ancients and moderns for fighting, as well as cocks, were fitted for the purpoſe of amuſement at ſo early a period. Pliny, however, informs us, (N. H. l. x. c. 21.) that at Pergamus, a city of Aſia, there was an annual exhibition of cock-fighting. But we derive no information from his account, when or where this practice commenced, or for what purpoſe, whether civil or religious, it was introduced. The Dardanii, a people of Troas, had on their coins the repreſentation of two cocks fighting: but as theſe coins are of a late date, the antiquity of this ſpecies of diverſion among the Dardanians cannot be inferred from them. Mr. Pegge ſuggeſts that, perhaps, it might have been introduced among them, and alſo at Pergamus, from Athens, where an annual feſtival, under the title of Ἀλεκτρυόνων ἀγὼν, was inſtituted by Themiſtocles, after the concluſion of the Perſian war. When this famous general was leading the Athenian army againſt the Perſians, he ſaw ſome cocks fighting, and took occaſion from this circumſtance to animate his troops by obſerving to them; "Theſe

"These animals fight not for the gods of their country, nor for the monuments of their anceſtors, nor for glory, nor for freedom, nor for their children, but for the ſake of victory, and that one may not yield to the other;" and from this topic he inſpirited the Athenians. (Vid. Ælian, Var. Hiſt. ii. c. 28.) If we can excuſe the barbarity of this inſtitution, it may be conſidered in ſome degree as commendable, becauſe it was an act of perpetual gratitude to the benevolent deity that preſented him with an occaſion of haranguing his ſoldiers with ſuch effect as to induce them ſucceſsfully to engage their enemies in battle, or at leaſt, as a permanent encouragement to his nation. As to the barbarity of the inſtitution, Ælian remarks, that cruelty and every kind of debauchery were ſo generally interwoven with the religious obſervances and ceremonies of theſe polite Athenians, that they would be but little ſhocked and offended by it on this account; or, however, not more ſo than the more ignorant barbarians of the oppoſite coaſt of Aſia, the Pergamenians or Dardanians. We may further obſerve, that the cock, on account of his vigilance, was ſacred to Apollo, Mercury, and Æſculapius; and for the ſame quality, in conjunction with his magnanimous and daring ſpirit, he was appropriated likewiſe to Mars. This was extremely oppoſite to the purpoſe and intention of the "Spectaculum," or public ſhow, exhibited by Themiſtocles; as theſe creatures, called by Columella "rixoſæ aves," were ſuppoſed to be more addicted to fighting than any others. The ſcene of engagement, however, or in modern phraſe, the "pit," was the theatre; and the ſport laſted one day. But others, as well as Themiſtocles, have taken the advantage of the fight of cock-fighting, and deduced from this circumſtance an argument for the incitement and encouragement of military valour. Socrates endeavoured in the ſame way to inſpire Iphicrates with courage. (Diog. Laert. ii. § 30.) Chryſippus alſo, in his book "De Juſtitia," ſays, "our valour is raiſed by the example of cocks." Lucian likewiſe (de Gymnas. ii. p. 295), introduces Solon, the great Athenian legiſlator, as addreſſing Anacharſis to the ſame purpoſe. Muſonius alſo, cited by Stobæus (Serm. 29), deduced the ſame kind of inſtruction from the battling of quails and cocks; and we are informed that the young men were obliged to attend the exhibitions of the theatre, in order to avail themſelves of this inſtruction. It further appears, that the other Greeks, as well as the Athenians, held a good fighting breed of cocks in high eſtimation, and often amuſed themſelves with this diverſion. We learn from Pliny (ubi ſupra), and Columella (viii. c. 2.), that the iſlanders of Delos were great lovers of this ſport; and Tanagra, a city of Bœotia, the iſle of Rhodes, Chalcis in Eubœa, and the country of Media, were famous for their generous and magnanimous race of chicken. The kingdom of Perſia was probably included in the laſt, from whence this kind of poultry was firſt brought into Greece; and if a judgment may be formed of the reſt from the fowls of Rhodes and Media, the excellency of the broods at that time conſiſted in their weight and bulk (as the fowls of that country were heavy and large), and ſuch as our ſportſmen call "ſhake-bags" or "turn-pokes." At Alexandria, in Egypt, they had a breed of hens, called Μονοσοροι, which produced the beſt fighting-cocks. Upon the whole, it ſhould ſeem, that at firſt cock-fighting was partly a religious and partly a political inſtitution at Athens; and was there continued for the purpoſe of cheriſhing valour in the minds of their youth; but it was afterwards perverted, both here and in other parts of Greece, to a common paſtime, without any moral, political, or religious intention; as it is now practiſed among us.

The Romans, who were prone to imitate the Greeks, followed their example in this kind of diverſion, without any good or laudable motives. Signior Haym (cited by Mr. Pegge,) thinks, that the Romans borrowed the paſtime from Dardanus, in Aſia; but it is needleſs to trace their derivation of it to ſuch a diſtance, more eſpecially as it was generally followed in Greece, and was not introduced among the Romans at a very early period. From a paſſage that occurs in Columella, (ubi ſupra) it appears probable that the Romans did not uſe the ſport of cock-fighting in his time; and he moreover ſpeaks of it in terms of ignominy, as an expenſive amuſement, unbecoming the frugal houſeholder, and as often attended with the ruin of the perſons that purſued it. The Romans ſeem to have been more acquainted with quails as fighting birds than with cocks. At length, however, they paired cocks, as well as quails, for fighting. The firſt cauſe of contention between the two brothers, Baſſianus and Geta, the ſons of the emperor Septimius Severus, happened, according to Herodian, (iii. § 33) in their youth, about the fighting of their quails and cocks; and, as they had often accompanied their father into Greece, they had probably ſeen and learned this paſtime there. It might naturally have been expected that, after the introduction of Chriſtianity into the Roman empire, when the bloody ſcenes of the amphitheatre were diſcarded, this barbarous and inhuman diverſion, which had a tendency towards cheriſhing ferocity and implacability in the minds of men, would have been reſtrained and gradually annihilated. Beſides, this paſtime has been the bane and ruin of thouſands here, as well as of thoſe "laniſtæ avium," cock-feeders, mentioned by Columella, whoſe patrimonial fortunes were entirely diſſipated and conſumed by it.

The cock is not only a very uſeful animal, but ſo ſtately in his figure, and magnificent in his plumage, that Pliny ſpeaks in high terms of his government among his own kind, and Ariſtophanes compares him to the king of Perſia. Such alſo is his tenderneſs to his brood, that he will ſcratch and provide for them with an aſſiduity almoſt equal to that of the hen; and ſuch is his generoſity, that, on finding a hoard of meat, he will chuckle the hens together, and without touching one morſel himſelf, will relinquiſh the whole to them. The cock was called *the bird*, κατ' ἐξοχην, by many of the ancients; he was highly eſteemed in ſome countries, and, in others, was even held ſacred; inſomuch that one cannot forbear regretting, that a creature ſo noble and ſo uſeful ſhould be ſo cruelly treated. It affords, however, ſome ſatisfaction, that the Αλεκτρυοφονια, if ſuch a word be allowed, or the maſſacre of Shrove-Tueſday, is now declining, and this circumſtance encourages the hope, that, in a few years, it will be totally diſuſed; but the cock-pit ſtill continues a reproach to the humanity of Engliſhmen, and to the benign religion which they profeſs.

This ſpecies of paſtime was probably brought into England by the Romans, but the preciſe period of its introduction has not been aſcertained. The bird was here before Cæſar's arrival; but Mr. Pegge, in his Reſearches, has found no notice of his fighting before the time of William Fitz-Stephen, who wrote the life of archbiſhop Becket, ſome time in the reign of king Henry II. William deſcribes the cocking as a ſport of ſchool-boys on Shrove-Tueſday, called "Carnilevaria." The theatre was the ſchool, and the maſter was the director of the ſport. From this time, the diverſion, however abſurd and barbarous, has continued amongſt us; it was followed, though diſapproved and prohibited, 39 Edw. III.; alſo in the reign of Henry VIII.; and A. D. 1569. By ſome it has been called "a royal diverſion;" and much encouraged both by Henry VIII. and

James I; but it was forbidden by one of the acts of Oliver Cromwell, March 31, 1654.

There are no documents that we are acquainted with to inform us in what state the art of fighting cocks existed to the reign of king Henry VIII. who, it is supposed, founded the celebrated national cock-pit at Westminster, afterwards renewed and encouraged by Charles II. whose pile cocks, the introduction of this monarch, are in high estimation among numerous breeders at this day. From that period annual mains have been fought at the royal cockpit in Westminster to the present time.

The institutors of this establishment enacted certain laws for the better regulation of these sports, the leading features of which, as belonging to this art, we shall here briefly describe.

There are three kinds of mains at present in use with cockers; the *long main*, which in general continues for a week, seldom or never longer; the *short main*, of a day or two, (both regulated by the same laws); and the *Welch main*: in the long main the cocks are generally the property of a joint subscription, or of only two individuals, and the cocks thus collected are chosen for the main, according to their weights, those being preferred, as a medium weight, from three pounds eight ounces to four pounds ten ounces, giving or taking an ounce on either side, though they are generally matched to a drachm weight. The cocks, which form the bye-battles in the main, become the objects of separate bettings, and are subject to the same weights and regulations. Cocks, whose weights are above four pounds eight ounces, are termed shake-bags or turn-outs, and are seldom matched against each other by weight.

The short-main lasts only for a day or two, the cocks being fewer in number, or the numbers are doubled for each day. The Welch main is generally fought for a purse, a gold cup, a fat hog, or some other prize; in this main all the fowls are restricted to a certain weight, *viz.* about four pounds four ounces: these are matched against each other, as shall be agreed upon, the winners again taking the winners, till they are reduced to a pair; then the winner of the last battle gains the prize.

Besides this there is also to be noticed the battle-royal, which consists in any number of fowls being put down together on the pit, and the last surviving fowl gains the prize.

Those species of fighting, called the battle-royal and the Welch main, are known no where in the world, as Mr. Pegge conceives, (ubi supra), but in this country; neither in China, where this species of diversion is very prevalent, nor in Persia, nor in Malacca, nor among the savage tribes of America.

The battle of the main always begins with fighting the lightest cocks; it is fair to feed them in any way you please after they are weighed; and those which, proportionately to their bulk, had been previously most reduced, or brought down, now have the opportunity of being fed and brought up again, thereby gaining upon the weight of their opponents; for the lightest cocks are found to be the first prepared by the artifices that are used to bring them to their wind and action.

The following articles are observed by the members of the cock-pit royal, for regulating the mains. "Articles of agreement, made the day of , one thousand eight hundred and , between : First, the said parties have agreed, that each of them shall produce, shew, and weigh, at the , on the day of , beginning at the hour of in the morning, cocks, none to be less than 3lb. 8oz., nor more than 4lb. 10 oz., and as many of each party's cocks that come within one ounce of each other, shall fight for a battle, that is each cock, in as equal divisions as the battles can be divided into six pits, or days play, at the cock-pit beforementioned; and the party's cocks that win the greatest number of battles, matched out of the number before specified, shall be entitled to the sum of , odd battle money, and the sum to be staked into the hands of Mr. before any cocks are pitted, by both parties. And we further agree, to produce, shew, and weigh, on the said weighing days, cocks for bye battles, subject to the same weight as the cocks that fight in the main, and these to be added to the number of cocks unmatched; and as many of them as come within one ounce of each other, shall fight for a battle; the number of cocks so matched, to be equally divided as will permit of, and added to each day's play with the main cocks; and it is also agreed, that the balance of the battle money shall be paid at the end of each day's play. It is also further agreed, for the cocks to fight in silver spurs, and with fair hackles; and to be subject to all the usual rules of cock-fighting, as practised at the cock-pit royal, Westminster; and the profits arising from the spectators, to be equally divided between both parties, after all charges are paid that usually happen on those occasions. Witness our hands, day of 18 ."

It is understood on all occasions, that battles for 5 *l.* and upwards must be fought in silver spurs, unless the contrary is expressly agreed upon, for this reason, that the battle is not so soon ended in silver, and the fowl has more opportunity of displaying his powers than in steel spurs. The setters to of the cocks are not permitted, by the general laws of cocking, to take up their fowls after they are put down upon the pit, unless either of the fowls touch the side of the pit, or are entangled in each other, or in the mat; in either case they may be handled and brought to the centre of the pit; if the fowl is thrown on his back with his legs upwards, and not touching the pit, it is lawful to turn him only; but it is not allowed, on any pretence, to remove feathers, &c. from the beak or eyes during the fight.

If either, or both cocks, through blindness, or any other cause, cease to fight, "the law is told," that is, a person counts twice twenty, when they may be handled and set to again; this telling of the law is repeated as long as both cocks fight; but ten only is counted at each interval after the first, previously to their being put together; either ceasing to peck, is told out by a person counting distinctly and audibly twice twenty, they are then set to beak to beak; if he now refuses to fight, ten is told, and, "once refused," announced; if he continues to refuse, ten more. "twice refused," and so on till he has refused ten different times, when he loses the battle; this is termed the *long law.* If a cock resumes his fighting at any period during the counting, in that case, in counting again, to begin the tens till the refusals make ten following each other. Should both be disabled, and refuse to fight, *before* the long law begins counting, it is a drawn battle, and neither wins; and should both refuse fighting during the telling of the long law, it is that cock's battle which fought last; but should he die before the law is told out, he loses the battle, notwithstanding the other did not fight within the law.

If any one desires to stop this telling him out, he may *pound him*, that is, he bets the cock will be beaten ten pounds to five shillings; in this case he must lay down his hat, handkerchief, glove, or something upon the pit, as a token of the challenge. When the *short law* is told by a person, distinctly counting *twice twenty*, and afterwards repeating the words, *will any one take it?* three times; if no one accepts

cepts the challenge during this ſhort law, the cock is beaten. It is neceſſary, when any one takes the poundage or bet, that he declares it, and alſo lays down ſomething on the pit as ſurety; when the cock muſt fight till death, and ſometimes moſt unexpectedly he recovers and wins.

Having deſcribed the natural origin of this race of birds, the hiſtory of the ſport, and its laws and regulations, we now proceed to conſider the general form and properties of the fighting cock, when in his greateſt perfection, according to the ideas we at preſent entertain.

The general outline of the fineſt cock, taken as a whole, nearly approaches that of a lengthened cone, excluding the legs and tail, the apex of the cone being the head, and the baſe the vent and belly; under ſuch external form, may exiſt the beſt properties of the cock; in deſcribing the beauties of particular parts, the head ſhould be ſmall, the beak ſtrong and pointed, the neck long, and at the ſame time ſtrong, the girth of the ſhoulders, cheſt, and body, broad, feeling broad to the graſp, and tapering again to the rump. The thighs and legs large and ſtrong, and rather long than ſhort; and it is conſidered a good point if he brings them cloſe up to his body, when held in the hands, inſtead of letting them hang looſely down.

The feathers, to amateurs, alſo afford a good criterion of judging of the ſoundneſs of the bird; where theſe lie cloſe to the ſkin, and compacted together, and feel ſhort and ſtiff to the touch, and ſhining and gloſſy in their exterior; ſuch is deemed a ſound feathered bird.

The colours moſt admired are the *reds* and the *duck-wings;* by the red, among cockers, is underſtood a cock with a *hackle* (that is, the feathers of the head and neck) red, and with the hackle generally correſpond the colours of the rump or *ſaddle.*

The *red cock* varies with a black breaſt and *ginger* wing, that is, of a gingerbread or tawny colour, and again with a black-breaſt and a dark wing; ſuch are *dark reds.*

The colour of the wing, as uſed among the amateurs in cocking, is ſometimes taken from the whole wing; as, where the wing is altogether of a ginger-red, excepting the flight, or primary feathers, which are dark, or a part of the wing, as in the duck wings, hereafter to be deſcribed.

The *light-reds*, are thoſe whoſe breaſts are wholly red, or red ſpotted with black, or black ſtreaked with red, and theſe receive their names according to theſe circumſtances, as, *ginger-breaſted, ſpotted-breaſted, ſtreaky-breaſted,* &c.

The *duck-wing* cock derives this name from a bar of ſteel-blue acroſs the greater coverts, like the faſcia acroſs the wild duck's wing; in this caſe it is obſerved, that the ſecondaries are exteriorly white, the hackle alſo white or pale-yellow, or cream-colour, as are the ſaddle-feathers, which correſpond, as we have before noticed, with the hackle.

In diſcriminating the individuals of this breed, it is farther uſual to deſcribe the colours of the breaſt and the ſhoulders; the breaſt may be *black*, or *ſpotted*, or *ſtreaked;* the ſhoulders may be *tawny*, or *dark-red*, or *birchen*, that is, of the colour of the twigs of a birch broom, or *ſilver-ſhouldered,* being nearly white.

The *yellow cock* is merely a variety of the duck-wing, from which it differs only in having the ſecondary feathers, or thoſe next the flight, dark, inſtead of white, which is not of unfrequent occurrence; the blue-bar in theſe cocks is ſometimes ſeen to vary to a light-brown.

The next colour to be noticed is the *dun;* theſe cocks, are in reality of a lead, or ſlate colour, and may be wholly ſo, or duck-wings, with the breaſt, flight, and tail, dun; or a *yellow-dun,* that is, a yellow cock with a dun flight, breaſt, and tail; by flight-feathers are underſtood the primaries, or firſt and ſtrongeſt feathers of the wing; the *red-duns* are red cocks with a dun breaſt, flight, and tail.

Black cocks are ſo coloured, ſome wholly ſo, others with birchen or brazen ſhoulders, which are almoſt the only varieties of this cock.

White cocks are either wholly white, termed *ſmocks*, or with red ſhoulders, which are termed *piles;* when theſe are ſtreaked with any colour in the hackle, breaſt, rump, or tail, they are then termed *ſtreaky-piles.*

If the pile-cocks have a mixture of dun (that is, lead colour on the breaſt and ſhoulders), they are called *dun-piles;* another variety of this fowl is the *cuckoo*, which is deemed rare, that is, a white fowl with the feathers variegated promiſcuouſly, or rather barred with black and yellow.

The *ſpangled fowl* is particularly rare; it is a red fowl, with the feathers tipt with white, or ſometimes white and black.

There is ſtill another breed of cocks we have to mention, called *hen-cocks*, from their feathers being ſhort, reſembling thoſe of a hen; their colour is generally brown, or ſpeckled, they are allowed to fight as well as any other, and to be as good game; we are totally unacquainted from whence originates this breed; in fighting, it frequently happens that they have an advantage, in being miſtaken by their antagoniſt cock for a hen, and frequently from this are enabled to get the firſt blow.

When any coloured fowl has the ſhoulder mixed with black, ſuch cock is denominated *beezy ſhouldered*, a term whoſe origin we are not acquainted with, probably from the French word *bis*, black, or duſky.

The legs, as forming part of the deſcription and character of the cock, ſhould alſo be noticed. Theſe are either yellow, blue, white, olive, or dark green, willow, or light-green, black, or carp-legged, a mixture of black and yellow; the beaks in general correſpond with the colour of the legs.

The eyes are alſo an object of attention, being a point of deſcription in the match-pile; the red, or ferret-eye (the *iris* being red); the pale-yellow, or daw-eye; the dark-brown, or ſloe-eye.

Other qualities of the cock remain to be conſidered, as they conſtitute important properties in the battle; theſe properties conſiſt in the ſpecific weight of the cock, in regard to his bulk, as a large cock may not only feel light in hand, but weigh light in the ſcale, his bone and fleſh being of a lighter quality, while others, though much leſs, ſhall outweigh him; and ſuch are commonly diſtinguiſhed by the phraſe, *lumpy cocks*, while the others are termed *corky*, or light, like cork, which is of more value in the match, as the larger cock has the advantage.

The conſtitution, or rather healthy condition, of the cock is alſo neceſſary to be known; this is more readily aſcertained than would be imagined; firſt, by the feather, as we have before ſtated, being ſound, and difficult to be drawn out, ſhort, ſmooth, hard, and ſhining; his crowing with a ſhrill and clear voice; his looking red in the face; if white, or pale, in that part, or if he pants much, and turns blackiſh after exerciſe, it is preſumed, with tolerable certainty, that he is diſeaſed and unſound; that he is unfit for the *pens* or the battle.

The next conſideration in the fighting cock is the ſpur; to hit well with the ſpur is as neceſſary as to have courage, or any other good quality, as without this all the other qualities may be thrown away; this, however, is not known from any exterior indication, but by actual trial, and is not confined to any particular colour or breed. The piles often are obſerved to carry a fatal ſpur, without having ſo much

 game

game as the other breeds, especially if the battle be of long duration.

And next of the game, or blood of the fowl; for by this term is indicated his courage, or rather his endurance of the battle; this property is so extraordinary in some of these animals, that they fight obstinately to the last, and by this means, though apparently beaten, gain the battle.

Action in fighting, to be excellent, should be rapid, but without hurrying; quick, but cautious; to *break well* with their adversary, that is, on the first onset to throw off, or parry the blow, and then to hit; for if they strike and hit together at the onset, it is not unusual to see the thigh or wing broken, or the spur pass through the body of one or both. It is of consequence also, that in the early part of the battle, they should strike without laying hold, and keep a distance, as laying hold in the beginning of the battle is almost useless, but not so when the first efforts are past, and they become a little weary.

It is usual for the cock to aim at the head with the beak, but his stroke is known to be more fatal when he lays hold of the point of the wing, as in this case the spur enters some part of the body or the wing, and disables the fowl more certainly.

A cock is said to fight *well at the foot*, when he has obtained an advantage, and follows it up till he has killed his adversary, never suffering him to rise after being once down.

On *Breeding*. A well-tried breed of cocks being obtained from actual observation of their powers are to be used as the stock to breed from, and it should be observed that it has been found injurious to breed from two old fowls; on one side or the other they should be young, and three or four hens are fully sufficient for one cock, and the hens should be all of one breed, and if the colours are somewhat alike so much the better, as they unite the more kindly.

The breeding-place should be well aired, and kept entirely free from other poultry; clear water, grass, gravel, and lime rubbish, an occasional change of food, as barley, oats, potatoes boiled, and sometimes a little meat, and toast and beer, are also to be recommended.

The hen-house should be perfectly dry and clean, and the *roost* with perches rather low, as otherwise the heavy fowls jar their feet in coming down and occasion them to swell and become crippled.

The *perches* should be carefully made of the proper size for the grasp of the foot, not being too large or too small, as in the former case the hind claw is brought forward, and he becomes what is called duck-clawed, and in the latter the breast-bone becomes crooked.

There are several injurious things to the health of the fowls, which should be carefully kept away from their breeding place, as any thing which tends to soil the water they drink; the keeping of pigs, ducks, or allowing them access to coal ashes, or any soapsuds, are found by experience to produce the roop; geese and turkies are injurious to fowls, by continually fighting and battering them, and should not be allowed to be near them.

The nests of the hens may be about a foot and a half from the ground, made in an earthen pan or dish of a proper size, and clean straw, rubbed up so as to render it soft. Hay is found by experience to be injurious to the eggs, and to more readily produce vermin; and its faint smell seems also not to suit them.

There should be nests for every hen, and even their number should be rather more than less than the number of hens, as otherwise they are apt to fight and disturb one another from the nests, and break the eggs.

One egg should be always left in the nest for them to lay to, and that should be marked, that it may be easily known. Also the eggs as they are laid should be removed from the nest and marked with the date of their being laid, and the hen laying them, and be placed in a box of bran, and now and then, if laid on the side, be turned over; they are, however, considered best placed with the small end downwards, as it has been found by experience that they keep better in this position, and the following reason is alleged for this effect, the shape of the shell, which is a reversed cone, forms a support to the yolk, and prevents its descending to the shell.

When a hen begins to cluck or be brooding, no more of her eggs should be saved, as from this time her eggs are apt to become imperfect, are frequently without yolks, and often without shells: besides, cockers have a notion that the fowl bred from a clucking hen will not show the same game and bottom as those produced by her first eggs.

If two clutches are wanted from any hen in one season, it is effected more certainly by putting her first clutch of eggs under a dunghill hen, and putting the game hen under a coop where the other hens are about her, till her heat is over, when she may be set at liberty; whereas by removing her, she is forgotten, and when brought back to the other hens fighting ensues.

The next or second clutch she might be allowed to sit upon herself.

When a cock takes a dislike to any brooding or other hen, she should be removed, as he would otherwise injure or destroy her.

About 12 eggs form a proper clutch, as the hen cannot well cover more. When the first chickens are hatched, they may be taken away and placed in a basket with flannel or wool by the fire-side, and be fed with crumbs of bread, and chopped eggs, boiled hard, till the rest are hatched; then they should be placed with the hen at night, as she otherwise might take a dislike and kill them.

The eggs being all hatched, at least, those that are sound and good, the hen and chickens should be conveyed into some dry place, where cats or vermin of any kind cannot get at them. The hen should be cooped to prevent her from wandering from the brood, and getting into wet and dirty places.

The chickens are best fed with crumbs of bread and hard boiled eggs chopped up with it, and this is occasionally changed with advantage for groats or grits, wheat, chopped raw meat, or new cheese and curds, till they are able to eat barley, as they are apt in a short time to cloy with any one kind of food, to pine and die. They should have clean water, at least once a day, and it should be placed out of the sun. About the end of the third or fourth week it is well to set the hen at liberty with her chickens, taking care that she is not annoyed by other hens.

One advantage attends bringing them up under the dunghill hen, which is, that she is less quarrelsome or subject to be disturbed by other hens.

It is a false notion of old times, that the chickens brought up under a dunghill hen will partake of her properties, which is well known by experienced breeders to be untrue.

It is advisable, when the chickens are at an age that their sexes can be distinguished, as at about six weeks or two months old, to select those intended to be kept and to destroy the rest, as the survivors thrive better, and it prevents the brood from being too much distributed, for it is better to purchase fowls for the spit than to keep these to the injury of the rest, unless where the sole object in breeding them is the table.

In

In about four months it is ufual for them to begin to crow, and this is the right time to cut their combs, as cutting them early is thought to prevent their fighting together, and they alfo lofe lefs blood than if cut later, when the difficulty of ftopping it is greater, as it is neceffary then to ufe the cautery, or a ftyptic, for the cautery cannot be conveniently applied between the two furfaces or lobes of the comb. In about a few weeks after this, or when they are fent to their walks, their gills and deaf ears may be taken off, by which term is underftood a loofe flefhy whitifh caruncle behind the ear. Some cut the comb clofe, called the "low comb;" others leave an arched portion which is termed the "high comb."

About this period of the life of the young fowl, a difafter frequently happens which fhould be carefully guarded againft; which is, that they will, without any apparent caufe, fight and deftroy each other, and this we think we have obferved to happen more frequently after rain than at other times; perhaps from their being wetted, foiled, and disfigured, they may appear ftrange to each other, and thus are led to begin fighting; at leaft this is the moft probable reafon that has occurred to us.

If this happens before they can with propriety be feparated for different walks, it will be found neceffary to purfue a certain meafure to prevent their fighting; this is ufually accomplifhed by feparating them after fighting and keeping them for fome time without food; another difcipline to prevent this evil confifts in holding the weakeft in your hand, while the ftrongeft fpurs and pecks him till he cries out, or by beating him with a glove or handkerchief, he will afterwards be fatisfied with being fubordinate for a long time; otherwife they are ever fighting and picking or peeling the fkin from the fkull often in a way that they never recover from, and fuch are called peel-pates, and are not allowed in a main.

This ftate of difcipline and fubordination will be promoted by the prefence of the old cock among them, who will fo interfere in their battles as to awe them to a more peaceable demeanour, and this the more effectually if all the hens are removed.

They fhould now, before they are fent to their walks, be marked, and a regular regifter be kept of them. The marks are generally made in the eyelid, noftril, or connecting membrane of the toes by cutting a notch in one or more of them; and are defcribed as right, left, or both eyes or noftrils out or in right or left feet.

Having premifed thus far in raifing them, it is now our bufinefs to fpeak of the moft appropriate walk, which is often among experienced cockers even in fome refpects not fufficiently attended to. Farm-houfes are not always good walks for the reafon above-mentioned, that the game chickens get battered by other fowls. Poor cottages, where they are generally walked, have this difadvantage, that they have not fufficient food; a clear air—good food—pure water, and perfect feclufion from other fowls are the beft requifites on a walk of this kind; at any rate it is proper before they are taken up for fighting that they fhould be feen, and fuch as want it be fed, or, as it is called, hand-fed.

At about a twelvemonth old they are termed *ftags*, and at two years old they are called *cocks*. It may be defirable to try the breed while they are yet ftags, in which cafe the leaft valuable are felected; fuch for inftance as are fhorter-legged than the reft, or are in any refpect deficient in their make; from thefe trials we may be led to prefume upon the courage and action of the reft of the brood, and for this purpofe the ftag may be fought againft a cock of the fame weight, to afcertain his qualities.

Short filver fpurs, in thefe trial-battles, are better than fteel ones, as they are not fo immediately deftructive; and a ftag that beats a cock of equal weight muft have undeniable good qualities, even though he afterwards wins no other battle.

At two years old he becomes a cock, as we have obferved, and is then fit for fighting in the main, or fingle battles. It ftill remains, however, ere we bring him on the ftage, to defcribe the regimen requifite to give him the greateft profpect of advantage, and a fuccefsful iffue to the conteft; as a well-prepared fowl will have the advantage of a fuperior one that is ill-fed, or not prepared.

The fowl is fuppofed to come from his walk in good condition; in which cafe, he will be too fat for fighting, and will have no wind till he is reduced. To effect this, abftinence from food and medicine are required for feven or eight days, before he can be brought to the pit, at leaft, fuch is the regimen purfued by our firft feeders, and is pretty generally as follows: His tail and fpurs being cut fhort, he is put into his pens, and the firft day receives no food; fecond, he has his phyfic, confifting of cream of tartar or jalap, or both united, in the dofe of about five grains of each; or if it be a very fat and large fowl, the dofe may be increafed to ten grains of cream of tartar. Thefe are given him mixed in frefh butter; this generally purges brifkly, and fcours out the inteftines. Immediately after the phyfic is given him, and before it affects him, he is placed on loofe ftraw or a grafs plat with another cock, and allowed to fpar with him. The hots, or muffles, being previoufly tied on their fhort fpurs. In this way he is exercifed till he is a little weary; he is then returned to his pens. Before putting him up it is neceffary to examine his mouth to fee if he has been pecked or wounded in the infide, as fuch wound is apt to canker. To prevent this, it is wafhed with a little vinegar and brandy; he now is allowed his warm mefs to work off his phyfic. This is a diet made of warm ale or fweet wort, and bread in it, with a little fugar-candy; or bread and milk and fugar-candy, a large tea cup full.

He is then fhut up clofe till the next morning, or about 24 hours. If the weather is cold, the room fhould be made warm, or a blanket placed over the pen: if in warm weather he may be clipped out for fighting; but if the weather be cold this is beft left till the time of fighting. The windows of the room fhould alfo be darkened, excepting at feeding times.

Early on the following morning, that is, about the third day, his pen muft be cleaned out from the effects of the phyfic, &c. and clean dry ftraw be given him; his feet alfo fhould be wafhed and wiped clean before he is returned to his pen: if his feet feel cold his pen fhould be made warmer.

He is next to be allowed fome cock-bread, that is, a fort of bread made of ingredients in the following proportions: About three pounds of fine flour and two eggs, and four whites of eggs, and a little yeaft; this is kneaded with a fufficiency of water for a proper confiftence, and is fent to the oven and well baked: fome add, as a great fecret, a fmall number of anifeeds, or a little cinnamon; of this bread, as much as would fill a tea cup, cut into pieces, is given him twice that day; and no water is then given him whatever, as it is conceived highly injurious at the early part of the feeding.

On the fourth day, early in the morning, he fhould receive half a tea cup full of good barley and a little water, in which a toaft has been fteeped fome time. Having eaten this, clean his pen, let him be fupplied with clean ftraw, and let his pen be uncovered for about an hour, while he

fcratches

ſcratches and picks the ſtraw. Some think it highly advantageous to prepare the barley for them, by beating and bruiſing it, and thus to take away the ſharp points of the barley, and the huſky ſhell or covering, which is then blown away.

In the afternoon, the ſame quantity of barley may be repeated, but no water.

On the fifth, or next day, he may have the bread as before, but three portions of it, and no water.

On the ſixth, or weighing day, very early in the morning, give him the bread, as before: he is then to be weighed, and afterwards a good feed of barley and water ſhould be given. Some hold it a valuable ſecret to give them fleſh, as ſheep's heart, for this and the ſucceeding day, chopped ſmall, and mixed with the other food.

On the ſeventh day, or day before fighting, early in the morning, let him have the ſame feed of barley; in the afternoon bread and the white of an egg boiled hard, and a little water.

On the eighth, or day of fighting, he may have a little barley, as about 40 grains; ſome recommend it to be previouſly ſteeped in port wine, which, we are not aſſured, is at all uſeful. If, at any period of the feeding, the food ſhould remain in his crop, no more ſhould be given him till it is removed, which a bit of apple or cheeſe will aſſiſt in digeſting: and ſhould the fowl dung looſe or purge, when not required, it may be counteracted, by giving him a little hemp-feed, which ſome ſteep in brandy. A little wheat or millet-feed may alſo be added to his food. Repeated trials have taught us that about 2 oz. may be taken away, or ſuperadded to the weight of a fowl for one day, by the above means without injury: about eight is as much as he ſhould ever gain or loſe in the whole.

He is next cut out for fighting, that is, his wings rounded, the hackle and ſaddle feathers cut ſhorter, the feathers about the vent cut cloſe off, and the curly feathers of the tail, leaving only the vane or fan, which is ſhortened about one-half. The ſpurs are now placed on his legs, and he is fitted for the battle: in placing his ſpurs on, they ſhould not be tied too tight, leaſt he be cramped, or too ſlack, leaſt they get looſe; for ſhould they come off, or even break, during the battle, they are not allowed to be replaced. The point of the ſpur ſhould be carefully obſerved to be neither to the outſide or inſide of the hock or heel, but exactly behind, and in a line with it; the hunckle or hock is taken as a guide for its direction, following that of the natural ſpur.

There remains for us to make one remark more to render theſe matters clear, which is, that, although eight days are found to be a ſufficient time to prepare a fowl for battle, yet, in a main, ten days are commonly taken for the purpoſe, purſuing a ſimilar treatment to the foregoing. The cocks are weighed on the eighth, and the lighteſt begin fighting on the tenth day, ſo that the larger cocks, which are to fight in the latter part of the main, and have been conſiderably reduced, are brought up again by a greater proportion of food than the medium quantity we have deſcribed, and which ought alſo to be adminiſtered oftener in the day. The ſucceſs of the main often depending upon the proper management of the latter fowls, much muſt be left to the ſkill and judgment of the feeder, who ought to be intimately acquainted with the nature and conſtitution of the fowl, that he may be enabled to bring him to the battle in the beſt poſſible health and condition, neither diſtreſſed by medicine or abſtinence, before he is weighed, nor rendered inactive by overfeeding afterwards, as, in either caſe, he has not a fair chance for his life.

Such is the art of cocking; if, by unveiling its myſteries and ſtripping it of diſguiſe, the purſuit becomes leſs alluring and ſeductive to the votaries of the cock-pit, we may have contributed to remove a temptation, the indulgence of which does not appear conducive to the improvement of the morals of mankind. However, it ſhould not be concealed that, conſidered as an art, for maintaining the genuine propenſities of a noble animal; it is entitled to the reſpect of naturaliſts.

"Cock-fighting," ſays Mr. Pegge, "is an heatheniſh mode of diverſion from the firſt; and at this day ought certainly to be confined to thoſe barbarous nations abovementioned; the Chineſe, Perſians, Malayans, and the ſtill more ſavage Americans, whoſe irrational and ſanguinary practices ought, in no caſe, to be objects of imitation to more civilized Europeans."

Cock, in *Mechanics. Figs.* 3 and 4, *Pl.* XIV. *Mechanics,* repreſent two of Handaſyd and Rudder's patent corked plug-cocks, of which A is the end to be driven into the caſk, and B the ſpout, as in common; C. *fig.* 3, is the plug, which has a triangular, or other ſhaped top, and is to be turned by a key, *fig.* 1, which has a ſimilar hole in it. To the part D, a hollow cylinder of braſs, *fig.* 2, is ſoldered; it has a hole in its top, correſponding with the key; in order to keep the plug down in its place, a ſmall ſpiral ſpring, E, is applied, the lower end of which acts on a collar in the plug, *fig.* 3, and the upper end againſt the top of the braſs cylinder, *fig.* 2; at the bottom of the cock at F, the plug does not paſs quite through the cock, but there is a hole at the bottom to pour in oil to the plug of the cock, which hole is then cloſed by a ſcrew.

Figs. 4 and 5, ſhow the application of the ſpring to a common cock, the plug of which is to be turned by a crutch or handle; the plug, *fig.* 5, is ſomewhat longer than the cock, and a ſpring, E, of two turns, is applied, ſo as to act between the bottom of the cock and the head of ſcrew F, ſcrewed into the plug; another part of this patent applies to the putting of a collar of cork round in a groove, G, *fig.* 5, in the plug, as a farther ſecurity againſt leakage.

In 1797, Mr. Joſeph Bramah took out a patent for various improvements in cocks, one of which is ſhown in *figs.* 6 and 7; the plug, *fig.* 6, is hollow, and has a hole, A, in its ſide; the end, B, is ſquare, to put on the handle D, by which it is turned; the cock unſcrews at E, *fig.* 7, for putting the plug in and out, and the ſquare end, B, of the plug comes through a hole in the end of the cock. The end, F, is inſerted into the caſk, and the water is brought to the inſide of the plug, *fig.* 6; it is plain, that when the plug is turned, ſo that the hole, A, correſponds with the hole through the ſpout G, *fig.* 7, the cock is open, and ſhut when they do not coincide, owing to the plug being turned part round; the advantage of this cock is, that the preſſure of the water always tends to puſh the plug farther into it, and by that means keeps it water-tight.

Fig. 8 is another cock, poſſeſſing the ſame advantages, for which Mr. Bramah took out a patent in 1783; A B is a cylindric braſs tube, the end, A, of which is ſcrewed into the veſſel, and the other end has a ſtuffing-box in it, for the poliſhed rod, D, to paſs through; one end of this rod has a knob, E, to move it by, and the other has a plug, F, on it, which fits into the conical end of the tube A B. The operation of opening the cock is puſhing the knob E, which opens the valve or plug, F, and permits the water to run out at the ſpout G. The ſtuffing-box conſiſts of a plate, *a*, with a hole through it, laid upon a ſhoulder near the end of the tube A B; and the end of the tube beyond that is ſcrew-tapped, into which is ſcrewed a plug, *b*, which has alſo a

 hole

hole through it for the rod, D, to pass through, and the part which projects beyond the tube is square, for the convenience of turning it by a winch; between this plate, *a*, and the plug, *b*, a small quantity of hemp, tow, &c. is put round the rod, and by screwing the plug, *b*, tight, it is made to embrace the rod so closely, as to prevent any water getting through.

Fig. 9 is the common ball-cock; the plug, A, of this cock is held in by a screw or rivet, in the common manner; it has a copper rod, B, fastened to it, to the other end of which a globular ball, D, of thin copper plate is soldered, which, by its buoyancy, gradually shuts the cock as the water rises in the vessel, and prevents its running over; and as the water in the vessel is drawn, and again sinks, the cock opens to let in more water.

Figs. 10, 11, 12, 13, 14, and 15, exhibit the sliding or sluice cock, common in breweries, distilleries, &c. A A (*figs.* 14 and 15), is a frame, whose internal edges are nicely polished; on each side of this frame a cast-iron plate, B (*figs.* 15 and 13), is screwed, which has a piece of pipe and a flaunch to connect it with the pipes which bring and carry away the liquor; in the cavity formed by the frame, A, *fig.* 15, a slider, D (*figs.* 15 and 12), is introduced, one face of which is well polished to make it fit close to one of the side-plates B, and it is farther pressed up by two steel springs, *a*, *a*, screwed to the back of the slider D, and acting against one of the side plates B; to the slider, D, a well polished rod, E, is attached, and passes through a stuffing box, F (*figs.* 15 and 11) similar to the one above described; to the other end of the rod, E, a rack, G, (*figs.* 15 and 10) is fastened, which works into a pinion L, (*fig.* 10) in the frame H, (*figs.* 10 and 15) supported by two uprights, I, I, screwed to the upper flaunches of the side plates, B (*figs.* 13 and 15). When the slider, D, is down, as in *fig.* 15, the hole through the side plate, B, is covered, and the liquor assists the springs, *a*, *a*, in pressing the slider close to the plate, and keeping it tight; but when the pinion, L, is turned by a winch, the slider is drawn up, and opens a passage for the liquor.

Cock, *in a watch or clock.* See Balance.

Cock *of a dial*, the pin, style, or gnomon. See Gnomon.

Cock *boats*, small boats used in rivers, or near the shore, which are of no service at sea, because too tender, weak, and small.

Cock, *black*, black grous or game. See Tetrao *tetrix*.

Cock, *bloody-heeled*. See Heeler.

Cock, *castrated*. See Capon, Cock *supra*, and Poultry.

Cock, *gor*, Gor-*cock*, is the moor cock, or red grous, Tetrao *scoticus*

Cock, *grubbing of a*. See Grubbing.

Cock, *high bearing*, is a term used with respect to fighting cocks; denoting one larger than the cock he fights. As a *low-bearing cock* is one overmatched for height.

Cock, *hybrid*, hybrid grous. See Tetrao *hybrida*.

Cock, *Indian*, the origin of our common poultry found wild in India. The Curassow-bird, Crax *alector*, has been called improperly the Indian cock, being an inhabitant of South America.

Cock *of the rock*, or *rock manakin*. See Pipra *rupicola*.

Cock *of the wood*, or *mountain*. See Tetrao *urogallus*.

Cock-*paddle*, in *Ichthyology*, a name by which the common lump-sucker is known.

Cock-*throppled*, a name given by dealers in horses to one whose wind-pipe is small, and bends like a bow when he bridles his head. See Horse and Hunter.

Cock, *wood*, wood-cock. See Scolopax *rusticola*.

Cock-*water* is a stream of water brought in a trough, through a long pole, in order to wash out the sand of the tin-ore into the launder, while it is bruising in the coffer of a stamping-mill.

Cocks, aboard a ship, are little square pieces of brass, with holes in them, and put into wooden shivers to keep them from splitting and galling by the pins of the blocks in which they move.

COCKADE, in French, *cocarde*, in *Military Language*, a ribbon worn in the hat. As a military mark it succeeded the scarf, which was formerly worn by the officers and soldiers belonging to the different nations of Europe, the principal of which, in respect of this mark, are distinguished in the following manner: Both in the British army and navy, the officers wear cockades of black silk ribbons, the non-commissioned officers, private soldiers, and marines, black hair ones. The French cockades are made of light blue, pink, and white ribbons, mixed together, and are called *tricolor*, or three-coloured. The Spanish cockade is red; the Prussian black; the Austrian black; the Russian green, and so forth. Under the old government of France, officers were not permitted to wear a cockade, unless they were dressed in regimentals. There are certain old regiments in the Prussian service, of which neither the officers nor men wear cockades. In this country the cockade, till of late years, was worn by military men of all ranks and descriptions, both with regimentals and without them. But, for reasons best known to those who have the regulation of such matters, a military man, when out of regimentals, is not at present distinguished or known from any other person.

COCKATOO, in *Ornithology*, a family of the psittacus, or parrot tribe, *Brachyuri*, *cauda æquali* of Gmelin, or those having the tail short, and equal at the end. There are nine species of the cockatoo kind; namely, the Crowned, Black, Banksian, Funereal, New South Wales, White, Red-vented, Molucca, and Yellow-crested. See Psittacus.

COCKATOON, a name given by some writers to the white cockatoo, Psittacus *sulphureus*.

COCKBURN, Catharine, in *Biography*, a lady of considerable literary attainments, was born in London in 1679. She was the daughter of captain Trotter, a native of Scotland, and commander in the navy, in the reign of Charles II., who died while his daughter was very young, leaving the family in narrow circumstances. In her own language, in writing, and in French, Miss Trotter was principally her own instructor; but she obtained some aid in acquiring the elements of the Latin tongue, and the first principles of logic; of the latter she drew up an abstract for her own use. She gave very early evidences of a poetic turn, and when she was but a mere child, surprised her friends with some extemporary verses on an incident that happened in the street. She was educated in the principles of Protestantism, from which, however, she was estranged, by her intimacy with some Roman catholic families. Considerable pains were taken to bring her back to the religion in which she had been brought up, but without effect. When she was only 17, she wrote a tragedy, entitled "Agnes de Castro," which was well received by the public, and acted with considerable applause at the theatre royal. Two years after she composed another tragedy, entitled "Fatal Friendship," which was represented at the theatre in Lincolns Inn Fields, and obtained for the author a considerable share of celebrity. This play is regarded as the most perfect of her dramatic performances. About this period she

wrote

wrote ſeveral other poetical pieces, ſome of which were intended for, and introduced on the Engliſh ſtage. Her genius, and the powers of her mind, were not confined to poetry; ſhe was devoted to metaphyſical ſtudies, and was a great admirer of the "Eſſay on the Human Underſtanding." When ſhe was but 22 years of age, ſhe vindicated the principles of Locke, againſt an attack made upon them by Dr. Thomas Burnet. To this work ſhe did not affix her name, as well from an apprehenſion that the public might be prejudiced againſt a metaphyſical treatiſe written by a woman, as from a ſort of dread of being known to Mr. Locke as his defender. In an anonymous addreſs to that great man, ſhe ſtyles her work "a bold and unlicenſed undertaking;" and declares, that though ſhe ventures to publiſh her defence of Mr. Locke, yet it was "not without much apprehenſion and awe of his diſpleaſure." Her name was not long concealed, and Mr. Locke wrote her a very kind letter of thanks; and through his relation, Mr. King, afterwards lord chancellor, he made her a preſent of ſome books. She was ſtill a Roman catholic, and is ſaid to have injured her health, by the frequent abſtinence and faſtings enjoined by that church. She was, however, no bigot, and exhibited the utmoſt liberality to thoſe who held different religious tenets; and, upon a full inveſtigation of the queſtion, ſhe returned to the communion of the church of England, from which ſhe never afterwards departed. This change occurred in 1707, and in the following year ſhe married Mr. Cockburn, a clergyman, who had taken orders; but his ſcruples concerning the oath of abjuration, required at the acceſſion of George I., obliged him to reſign his employment as a clergyman, and to undertake the laborious office of aſſiſtant to a ſchool. He now found much difficulty in maintaining his family; but Mrs. Cockburn applied herſelf with great aſſiduity to the important duties of wife and mother. In the year 1726, ſhe again became the defender of Mr. Locke, whoſe opinion with regard to the reſurrection of the ſame body, had been controverted by Dr. Holdſworth. About this period Mr. Cockburn had overcome thoſe ſcruples which drove him from the church, and was invited to take the office of miniſter to an epiſcopal congregation at Aberdeen. Mrs. Cockburn wrote "Remarks upon ſome Writers in the Controverſy concerning the foundation of Moral Duty and Moral Obligation," which were publiſhed in the "Hiſtory of the Works of the Learned." She next drew up a confutation of Dr. Rutherford's "Eſſay on the Nature and Obligation of Virtue," in vindication of the contrary principles and reaſonings enforced in the writings of the late Dr. Clarke. This was publiſhed by Dr. Warburton, to whom ſhe had ſent it in MS. and who wrote a preface on the occaſion, in which he ſays, that "it contains all the clearneſs of expreſſion, the ſtrength of reaſon, the preciſion of logic, and attachment to truth, which make books of this nature really uſeful to the common cauſe of virtue and religion." The merit of this performance, the vivacity, acuteneſs, and ſtrength which were diſplayed in it, in the diſcuſſion of ſome of the moſt intricate and abſtruſe queſtions, excited the curioſity of the public reſpecting the concealed author. Her friends now ſet on foot a ſubſcription to publiſh all her works, in which ſhe readily concurred, but ſhe did not live long enough to diſcharge the office of editor; this was afterwards undertaken and executed by Dr. Birch. She died on the 11th of May, 1749, in the 71ſt year of her age, having ſurvived her huſband only about four months. In early life Mrs. Cockburn was celebrated for beauty, as well as for her genius, and other accompliſhments. Her figure was not prepoſſeſſing, but ſhe was diſtinguiſhed by the unuſual vivacity of her eyes, and the delicacy of her complexion. She was ſtrictly virtuous, benevolent, and generous, as far as her ſtraitened circumſtances would admit. In the year 1751, her works were publiſhed in two vols. 8vo. by Dr. Birch, who ſays of the author, that "her abilities as a writer, and the merit of her works, will not have full juſtice done them, without a due attention to the peculiar circumſtances in which they were produced; her early youth, when ſhe wrote ſome; her very advanced age, and ill ſtate of health, when ſhe drew up others; the uneaſy ſituation of her fortune during the whole of life; and an interval of nearly 20 years in the vigour of it, ſpent in the care of a family, without the leaſt leiſure for reading or contemplation. After which, with a mind ſo long diverted and encumbered, reſuming her ſtudies, ſhe inſtantly recovered its entire powers, and in the hours of relaxation from her domeſtic employments, purſued, to their utmoſt limits, ſome of the deepeſt inquiries of which the human mind is capable." Birch. Biog. Brit.

Cockburn *iſlands*, in *Geography*, a group of ſmall iſlands that lie off the N.E. coaſt of New Holland, S.W. of Cape Grenville, which lies in S. lat. 11° 58′, W. long. 217° 38′.

COCKBURNE, a townſhip of America, in the northern part of New Hampſhire, and the county of Grafton, on the E. bank of Connecticut river, S. of Colebrooke.

Cockburne, William, in *Biography*, an ingenious and learned phyſician, flouriſhed the latter part of the 17th and beginning of the laſt centuries. He was for ſome years phyſician to the royal navy, where he acquired a knowledge of the ſcurvy, and other diſeaſes incident to ſailors. Quitting the navy, he came to London, where he ſoon diſtinguiſhed himſelf by his ſuperior ſkill and abilities, and was thence aſſociated with the college of phyſicians, made a fellow of the royal ſociety, and phyſician to king William. His works are a "Treatiſe on Sea Diſeaſes, explaining their Nature, Cauſes, and Cure, to which is added an Eſſay on Bleeding in Fevers." This book has been frequently re-printed, and was early tranſlated into the German and French languages. The principal cauſe of ſcurvy is the diet, to which ſailors are neceſſarily confined in long voyages. Medicine can do little in the cure, which can only be effected by a diet of freſh proviſion, and taking the ſick on ſhore. Fevers are to be cured by emetics and purges, and not by ſudorifics, which, by waſting the fluids, occaſion coſtiveneſs, to which ſailors are much inclined, from feeding on biſcuit. He defends the uſe of the Peruvian bark, which many at that time denied. "Profluvia Ventri," 1702, 8vo., afterwards tranſlated and publiſhed in 1721, under the title of "A Cure of Looſeneſſes." "The Symptoms, Nature, Cauſes, and Cure of Gonorrhœa," London, 1713. 8vo. That it may exiſt, he contends, without any taint of the venereal diſeaſe. The cure is to be effected by giving firſt purges, and afterwards terebinthinate medicines. "Œconomia Corporis Humani," London, 1695, 8vo. Neither the pulſe nor urine, he ſays, afford any certain indices of the ſtate of fever: neither is perſpiration burſting out ſpontaneouſly, often critical; it is ſtill leſs ſo when excited by warm medicines and drink. This work was much noticed in its time; but more accurate treatiſes on the ſubject have occaſioned it to fall into neglect. Haller. Bib. Med. Eloy. Dict. Hiſt.

COCK-CHAFFER, in *Entomology*, the *ſcarabæus melolontha* of Linnæus, and *melolontha vulgaris* of Fabricius. The colour is teſtaceous brown, with the thorax hairy; tail inflected, and a triangular white ſpot at each inciſure of the abdomen.

Inhabits the northern parts of Europe, and is highly injurious to agriculture. The larva is ſoft and grey, wi

 the

the head and legs protected by a shelly covering of a yellow brown colour. While in the larva state, which continues for the space of three years, it devours the roots of grass, corn, and other vegetables. This mischievous creature subsists also on the leaves and tender buds of trees, and is from that circumstance denominated the *tree-beetle.* They are eagerly sought after, and devoured by crows, rooks, and other birds, as well as animals: it is the larva of this insect that is so frequently turned up in ploughing, and in quest of which the crows are often seen following the track of the plough-shares.

COCKER, a river of England, which runs into the Derwent at Cockermouth.

COCKERINGS, an exaction or tribute in Ireland, now reduced to chief rents.

COCKERMOUTH, in *Geography*, a borough town of Cumberland in England, derives its name from its situation at the mouth of the river Cocker, which separates it into two parts, and then falls into the Derwent, near the western extremity of the town. The streets are spacious, but irregularly built; yet many of the houses are neat, especially those on the acclivity towards the castle. The moot-hall, market-house, and shambles, have an ancient gloomy appearance, and, like most public buildings in the northern towns, prove a considerable obstruction to passengers, from being situated in the midst of a principal street. The church, which is spacious, but has no aisles, was rebuilt of free-stone in the year 1711, with the exception of the ancient tower. Several schools have been founded by subscriptions and bequests: and a dispensary for the relief of the indigent poor was established in 1793, to the benefit of which several thousand persons have been admitted. The ruins of the castle occupy the summit of an artificial mount, raised on a precipice above the Derwent, near its confluence with the Cocker. It appears to have been a fortress of great strength and extent, of a square form, and guarded by square towers: the compass of the wall measuring almost six hundred yards. It was anciently the baronial mansion of the lords of Allerdale; and is generally affirmed to have been built within a few years after the conquest, by Waldeof, the first of those lords. Cockermouth was anciently a hamlet to Brigham, but was constituted a distinct parish in the reign of Edward III. It has only enjoyed the privilege of representation in parliament since the year 1640, except one return made 23 Edward I. The right of election is in the inhabitants having burgage tenure, whose number is 165. The parts of the town, on each side of the Cocker, are connected by a bridge of one arch: on the north side is an artificial eminence, called Toot-hill, resembling the large barrows found in many parts of England. The hills on the opposite side of the Derwent, in this neighbourhood, are of a kind of calcareous stone, almost wholly composed of shells of the anomia genus. Cockermouth is 305 miles N. from London; has a weekly market on Mondays: the population under the late return was nearly 3000, the number of houses 433. The chief manufactures are hats, common woollen cloths, shalloons, checks, and coarse linens. Hutchinson's Hist. of Cumberland.

COCKERMOUTH, a town of America, in Grafton county, New Hampshire, about 15 miles N.E. of Dartmouth college. It was incorporated in 1766, and in 1775 contained 118 inhabitants, and in 1790, 373.

COCKET, or COCQUET, a seal belonging to the king's custom-house.

COCKET, or *Cocquet*, is a scroll of parchment, sealed and delivered by the officers of the custom-house to the merchants, upon entering their goods; certifying that the goods were customed. It likewise gives name to an office appointed for this purpose.

The same word is also used in the statute of bread and ale, 15 Hen. III. in which is mentioned *cocket-bread*, among several other kinds; it seems to have been hard sea-biscuit, which, perhaps, had then some cocket, mark, or seal; or else was so called from its being designed for the use of the cockswains or seamen.

COCKING *Cloth*, a device for the catching of pheasants. It consists of a piece of coarse canvas, about an ell square, dipped in a tan-pit to colour it; and kept stretched by two sticks, placed from corner to corner, diagonal-wise; a hole being left to peep through. The sportsman then, being provided with a short gun, carries the cloth before him at arm's-end; under cover of which, he may approach his game as near as he pleases: when near enough, he puts the nosle of his gun through the hole, and shoots.

COCKLE, in *Botany*. See AGROSTEMMA *githago*, and LOLIUM *temulentum*. See also DARNEL-*grass*.

COCKLE, in *Conchology*. See CARDIUM. Many fossil shells, known under this name, are found lodged in the British strata; *e. g.* within the soil of Norfolk, in the lime-stone strata of Derbyshire, in the free-stone quarries upon King's down, near Bath, &c.

COCKLE-*stairs*. See STAIRS.

COCKLE-*shell Bay*, in *Geography*, a bay on the east coast of the island of St. Christopher. N. lat. 17° 22′. W. long. 62° 22′.

COCK-KNEE STONE. See ECHINUS.

COCKPIT, a sort of theatre, whereon game-cocks fight their battles. The cockpit is usually a house or hovel, covered over: they fight on the clod, or green sod; which is generally marked out round, and encompassed with seats, one above another. See COCK *of the Game*.

COCKPIT, in a man of war, is a place on the lower floor, or deck, abaft the main-capstan, lying between the platform and the steward's room; where are subdivisions or partitions, for the purser, the surgeon, and his mates.

COCK-*roach*, in *Entomology*. See BLATTA *orientalis*.

COCKROAD, a contrivance for the taking of woodcocks. This bird lies close by day, under some hedge, or near the root of an old tree, to peck for worms under dry leaves, and will scarce stir out, unless disturbed; as not seeing his way so well in the morning; towards the evening he takes wing to seek for water, flying generally low; and when he finds any thoroughfare in a wood, he ventures through it.

To take them, therefore, they plant nets in such places; or, for want of such places ready to their hands, they cut roads through woods, thickets, groves, &c.

These roads they usually make thirty-five, or forty feet broad, perfectly straight and clear; and to two opposite trees they tie the net, which has a stone fastened to each corner. Then, having a stand, or a place to lie concealed in, at a proper distance, with a stake near the same, to fasten the lines of the net to; when they perceive the game flying up the road, they unwind the lines from off the stake; upon which, the stones drawing it down, the birds are entangled in the same.

COCK'S-*comb*, in *Botany*. See CELOSIA *cristata*, C. *margaritacea*, C. *coccinea*, and RHINANTHUS *crista galli*.

COCK'S-*foot grass*. See DACTYLIS.

COCK'S-*head*. See HEDYSARUM *onobrychis*.

COCKSON, THOMAS, in *Biography*, an engraver, in all probability an Englishman, by whom we have a great many portraits, executed with the graver in a neat, but rather a stiff manner. Amongst other prints by him are the following: King James I. sitting in parliament, a large print; king Charles I. sitting in parliament, likewise a large print; the

the princefs Elizabeth, daughter of James I.; Samuel Daniel, dated 1609: Concini, Marquis d'Ancre, 1617, &c. Strutt Heinecken.

COCKSWAIN, Cockson, or Coxen, an officer on board a man of war, who hath the care of the boat or floop, and all things belonging to it. He is always to be ready with his boat's gang or crew, and to man the boat on all occafions. He fits in the ftern of the boat and fteers; and hath a whiftle to call and encourage his men.

COCLES, Publius Horatius, in *Biography*, a celebrated Roman, defcended from one of the Horatii who fought againft the Curiatii. In the year of the city 247, he oppofed the whole army of Porfenna, king of the Etrufcans, at the head of a wooden bridge acrofs the Tiber, which joined the Janiculum to the city. When the bridge was deftroyed, Cocles, though wounded by the darts of the enemy, leaped into the Tiber, and fwam with all his armour on his back. A brazen ftatue was raifed to him in the temple of Vulcan, by the conful Publicola, for his great fervices. He had the ufe of only one eye, as the name Cocles fignifies. Livy. Val. Max. Virgil.

Cocoa *Iflands, Great and Little*, in *Geography*, a group of iflands, fo called from their being clothed with cocoa-nut trees of unufual luxuriance, and fituated in the Indian ocean, to the north of the Andaman iflands, about N. lat. 14° 20′. E. long. 93°. Thefe iflands are fmall, flat, and fwampy; they are uninhabited, and deftitute of good water. In fteering between the Southern Cocoa, and the north end of the ifland of Andaman, Port Cornwallis opens on the eaft fide of the latter.

Cocoa-*nut Ifland*, or Cocos, a fmall ifland at the entrance of Carteret's harbour, on the S. E. coaft of New Ireland. Between this ifland and Leigh's or Laig ifland, there is fhoal water, and each of them forms an entrance into the harbour; the S. E. or weather entrance is formed by Leigh's ifland, in which is a rock appearing above water, called by Capt. Carteret "Booby rock:" the paffage is between the rock and the ifland, nor is the rock dangerous, there being deep water clofe to it. The N. W. or lee entrance, is formed by Cocoa-nut ifland, and this is the beft, becaufe it has good anchorage, the water in the other being too deep. Capt. Carteret entered the harbour by the S. E. paffage, and went out of it by the N. W. At the S. E. end of the harbour there is a large cove, which is fecure from all winds, and fit to haul a fhip into. Into this cove a river feemed to empty itfelf. In the N. W. part of the harbour, there is another cove, fit for a fhip to haul into, fupplying good water, and very convenient both for wooding and watering. The higheft part of the ifland of Cocos is not above 75 toifes above the level of the fea, and is formed of calcareous ftones. This ifland is terminated on the S. E. and N. W. by the fame kind of ftones. It is covered by large trees, which always preferve their verdure. The ifland produces fig-trees and vines of different fpecies in great abundance; but cocoa-nuts are fcarce. Cocos and Laig abound with infects of various forms and colours.

Cocoa-*nut*, in *Botany*. See Cocos.

Cocoa-*plum*. See Chrysobalanus.

Cocoa-*point*, in *Geography*, a cape on the coaft of the ifland of Tinian.

COCOI, in *Ornithology*, a beautiful bird of the ardea or heron tribe, the blue heron of Albin and other Englifh writers. This fpecies inhabits Brafil and Cayenne; its length is about three feet, and it is fpecifically diftinguifhed by having the hind head, pendent creft, and back cinereous; neck beneath fpotted with black, and the fides of the head black. This is the *foco* of Buffon, and *ardea cayanenfis criftata* of Briffon.

COCOMARICOPAS, in *Geography*, a kind of favages in Spanifh North America, who live near the banks of the river Colorado, and who are dextrous in fwimming acrofs, holding in the left hand a piece of wood, which fupports their arms and burthen, and fteering with the right; while the women, fupported by a kind of petticoat of bafket work, upon which they place their children, pafs in like manner.

COCONATO, a town of Italy, in the principality of Piedmont; 4 miles S. of Crefcentio.

COCONOR. See Kokonor.

COCOON. See Silk.

COCORTO. a town of Afia, in the country of Thibet; 50 miles S. S. W. of Tchontori.

COCOS, in *Botany*, (according to Cafpar Bauhin, the fruit is called by the Portuguefe *coco*, or *coquen*, from the three holes at the end of the fhell, which give it the appearance of a monkey's head.) Linn. Gen. 1223. Schreb. 1692. Juff. 38. Vent. 2. 128. (Coccos; Gært. 21. Cocotier; Encyc.) Clafs and order, *monœcia hexandria*. Nat. Ord. *Palmæ*; Linn. Juff. Vent. Male and female flowers on the fame fpadix. *Cal.* Spathe univerfal, one-valved, fpadix branched. *Males.* *Perianth* three-leaved; leaves almoft trigonous, fmall, acute, concave, coloured. (fix-leaved; Gært.) *Cor.* Petals three, egg-fhaped, acute, fpreading (none; Gært.) *Stam.* Filaments fix, the length of the corolla; arrow-fhaped. *Pift.* Germ fcarcely vifible, abortive; ftyles three, fhort; ftigma obfolete. *Females.* *Perianth* three-leaved; leaves roundifh, concave, converging, coloured, permanent. *Cor.* Petals three, refembling the leaves of the calyx, permanent. *Pift.* Germ fuperior, roundifh or egg-fhaped, (three-celled; Gært.); ftyle none; ftigmas three. *Peric.* Drupe very large, coriaceous, roundifh, obfcurely triangular; nut large, fomewhat egg-fhaped, acuminate, one-celled, valvelefs, hard, obtufely triangular, perforated by three holes; kernel hollow.

Eff. Ch. *Males.* Calyx three-leaved; corolla three-petalled, ftamens fix. *Females.* Cal. and Cor. as in the males; ftigmas three, drupe coriaceous.

Sp. 1. C. *nucifera*. Cocoa-nut tree. Linn. Sp. Pl. Mart. 1. Lam 1. Jacq. Amer. 277. tab. 168. Pict. 135. Gært. tab. 4, 5. Lam. Ill. tab. 894. (Palma indica coccifera angulofa; Bauh. Pin. 508. Nux indica; Lob. ic. 2. p. 273. Tenga; Rheed. Mal. 1. tab. 1, 2, 3, 4. Calappa; Rumph. Amb. tab. 1, 2.) "Unarmed; fronds pinnated; leaflets folded back, enfiform." *Trunk* from forty to fixty feet high, of a moderate thicknefs in proportion to its height, ftraight, naked, marked with the fcars of fallen leaves. *Leaves* from ten to twelve, cluftered, forming a terminal head; upper ones erect, middle ones horizontal, lower ones rather drooping, from ten to fifteen feet long, about three feet broad, pinnated; common petiole naked near its bafe; leaflets numerous, petioles in two ranks, which are a little inclined to each other. *Spathes* oblong, acute, opening on one fide. *Flowers* yellowifh white, feffile, in a branched panicle; female ones near the bafe of the branches; male ones more numerous, covering the upper part. *Fruit* nearly as large as a man's head, cluftered, egg-fhaped, obfcurely three-fided, with rounded angles, umbilicated at both ends, with three obtufe projections; external rind thin, even-furfaced, very tough; inner one extremely fibrous; fhell of the nut nearly globular, hard, with three raifed fpurious futures, and three holes at the bafe clofed with a black membrane; kernel white, in firmnefs and tafte refembling that of the hazel-nut, hollow, containing a milky fluid. This kernel in fome plants is near an inch thick, enclofing about a pint of fweet, delicate, wholefome refrefhing liquor. A native of Africa, of the Eaft and Weft Indies, and of South America, in a fandy foil; bearing

fruit

fruit twice or three times a year. Travellers, from the time of Dampier to the prefent day, are profufe in their praifes of this tree, and of the various ufeful purpofes to which it is applied by the inhabitants of the warm climates, in which it is indigenous. Its trunk is made into boats, rafters, the frames of houfes, and gutters to convey water. The leaves are ufed for thatching buildings, and are wrought into mats, bafkets, and many other things for which ofiers are employed in Europe. They are alfo written upon by the Eaft Indians as a fubftitute for our paper and parchment. The fibrous coat or hufk of the fhell, after being foaked in water, is beaten into oakum, fpun into a variety of yarns, woven into fail-cloth, and twifted into ropes and cables even for the largeft fhips. For thefe purpofes it is preferable to hemp on account of its greater durability. (fee COIR). The woody fhell itfelf, or nut which enclofes the kernel, is polifhed and formed into goblets, powder-boxes, and various kinds of cups. In Siam it is generally employed as a liquid meafure, and its capacity is determined by filling it with cowries (cypræa moneta: Linn.) fmall univalve fhells current in that country inftead of coined money. Thus there are cocoas of 1000 cowries, of 500, &c The kernels, preffed in a mill, yield an oil, which is faid to be the only one ufed in the Indies at the table. When recent it is equal in goodnefs to the oil of fweet almonds; but it foon becomes rancid, and is then employed only by painters. If the end of the young fpathes be cut off, or the body of the tree be bored, there exudes from the wound a white, fweet liquor, which is collected by the natives in pots, properly tried for the purpofe; but by this operation the tree is inevitably rendered barren: the juices neceffary for the ripening of the fruit being entirely exhaufted. The liquor, thus procured, is called palm wine, and is a favourite beverage in the country. It is very fweet when frefh; kept a few hours, it becomes more poignant and agreeable; but the next day it begins to grow four, and in the fpace of twenty-four hours is compleat vinegar. By diftillation it produces a tolerably good brandy, or as it is there called arack, more efteemed than that obtained from rice. Boiled with quick-lime, it thickens into the confiftence of honey; and after long evaporation, acquires the folidity, and in fome degree the thicknefs of fugar. As fuch it is ufed by the confectioners, but is much inferior to the produce of the fugar-cane. The tender leaves, before they fully expand, are fometimes eaten in place of cabbage and other culinary greens; but as this luxury can be obtained only by the deftruction of fo valuable a tree, it is generally thought too expenfive a treat, except in thofe parts of the country where the plantations are numerous. 2. C. *butyracea*, Linn. jun. Supp. 454. Mart. 2. Lam. 2. (Pindova; Pif. Braf. 125. Pindoba; Rai. Hift. 1361.) "Unarmed; fronds pinnated; leaflets fimple." A loftier tree than the preceding fpecies, with a larger head. *Univerfal fpathe* from four to fix feet long, cylindrical-oblong, leffened at both ends, woody; even-furfaced within; rendered uneven on the outfide by numerous, longitudinal parallel projections, a little remote from each other about the middle of the fpathe, but approaching, and almoft united near the fummit; fplitting longitudinally, and falling off after the expanfion of the fpadix. *Spadix* the length of the fpathe, branched; branchlets a foot long, quite fimple, much crowded, one or two in each palm, containing only male flowers; fix or eight others, both male and female. In thofe which have only males, each of the flowers is fupported by a fmall, fomewhat egg-fhaped, rigid bracte; leaves of the proper perianth three, refembling fcales, very fmall, oblong, flattifh, a little united at the bafe, rather erect; petals three, linear, roundifh, leffened at both ends, fix or eight lines long, bent different ways above the middle, very white, fucculent, flightly connected at the bafe, alternating with the calyx-fcales, even furfaced; filaments fix, filiform, three times fhorter than the petals, inferted into the receptacle, fomewhat united; anthers linear, the length of the filament, verfatile, bifid at the bafe, two-celled; pollen refembling fawduft, white, very fmall. Thefe flowers fall off at the irruption of the fpadix, or on the leaft touch, making a great heap under the tree. Male flowers of the androgynous fpadixes fimilar to the former, but continuing longer; thofe intermingled with the females, thinly fcattered, but in the upper part, where there are no females, much crowded; petals thinner; filaments fhorter; anthers with two horns. Female flowers crowded in an imbricate manner; bractes triple, rather loofe, quite flat; leaves of the calyx three, hard, cartilaginous, large, egg-fhaped, concave, broad and fomewhat rounded at the bafe, nearly covering the other parts of the flower; petals three, white, flefhy, refembling the leaves of the calyx, but fhorter and thinner; nectary corolla-fhaped, tubular, very white and very thin, three times fhorter than the petals, furrounding the greateft part of the germ; germ egg-fhaped, rather acuminate, quite fmooth, the length of the corolla; ftyle fcarcely any; ftigmas three, rather long, even furfaced on the outer fide, roughifh on the inner one, fomewhat erect. *Drupe* inverfely egg-fhaped, obfcurely trigonous, one-celled, fucculent, furrounded by the permanent calyx and corolla; rind cartilaginous; pulp fibrous; nut dry, very hard, flightly ftriated, with fmall longitudinal lines, convex on one fide, flattifh on the other, oblong, a little acute at both ends, perforated at the bafe with three oblique holes; kernel cartilaginous, very hard, with the flavour of that of C. nucifera. A native of South America, where the inhabitants obtain from the imperfectly ground nuts, without preffure, or the application of fire, and by fimple maceration in water, a kind of butter which fwims at the top, the heavier parts finking to the bottom. All the butteraceous matter is extracted by the third maceration. It does not, however, acquire the confiftence of butter in a temperature, above the twentieth degree of Reaumur; at the twenty-third it is perfectly liquid like other oils. The fucculent pulp is rather fweet, very mucilaginous, and excellent for fattening hogs. The oil or butter procured from the kernel, is in conftant ufe among the Indians of South America as an article of food, and as a medicine, while it continues frefh, but is rancid and noxious when old. 3. C. *guineenfis*, prickly pole. Linn. Syft. Nat. 2. Mant. p. 137. Mart. 3. Lam. 3. (Bactris minima; Gært. tab. 139. fig. 5. B. minor fructibus fubrotundis; Jacq. Amer. tab. 171. fig. 1. Palma fpinofa minor; Sloane. Jam. Hift. 2. p. 121. P. americana fpinofa; Baub. Pin. 507. Pluk. Alm. tab. 103. fig. 1. L. Avoira caune; Aubl. Guian. obf. 97. Autara; Marg. Braf. 64. bad.) "Whole plant prickly; fronds diftant; root creeping." *Root* knotty, cylindrical, thicker than the trunk, fhort, bent horizontally directly below the furface, prefently putting out another trunk fo as to form a thicket, whilft it fixes itfelf firmly in the foil by flender fibrous roots. *Stem* about ten feet high in open fituations, fomewhat higher in woods, about an inch in diameter, erect, armed in its whole length with numerous fpines as fharp as needles. *Leaves* pinnated, diftant, common petiole embracing the ftem, prickly; leaflets enfiform, flat, acuminate, fhining, with numerous fcarcely perceptible fpines at their edges, and a few fcattered larger ones on both furfaces. *Spathes* axillary, folitary, fpreading, permanent after the maturity of the fruit. *Flowers* pale yellow, fcentlefs, calyx many times fmaller than the corolla, fometimes three-leaved; corolla triquetrous, frequently three-cleft almoft to the bafe. *Drupes* roundifh, dark purple, about the fize of a common cherry; yielding an acidulous juice, of which the Americans make a kind of wine; eatable, but not pleafant, and affording food chiefly to the wild hogs. Jacq. and Browne. *Drupe* roundifh, fomewhat depreffed, fucculent, acidulous; rind coriaceous; nut fomewhat globular, hard as ftone, very thick, roughened on all fides by obfolete tubercles, ftamped about the middle with three holes, ftriated in rays at their mouths; two fmaller ones not paffing through the fhell; the other pervious, leading to the central cell. *Seed* conoid, horizontally decumbent, tubercled, brown, with a very prominent papilla at the bafe of the cone; albumen flefhy, friable; with a large cavity in the centre; embryo awl-fhaped, horizontal, fituated within the papilla. A native of the Weft Indies and of South America. The trivial name given by Linnæus in the firft mantiffa, and continued by all fubfequent authors, was probably a mifprint for guianenfis; canes are made of the trunk, ftripped of its bark; they are very light, knotty, black, and fhining. The French call them cannes de Tobago, under which name they are fometimes imported into Europe. In allufion to their ufe as walking canes, Jacquin named this palm, *Bactris* απο του βακτρου. 4. C. *aculeata*. Great macaw-tree. Mart. 4. Swartz. Prodr. 151. Brown. Jam. 344. n. 7. Sloan. Jam. 2. 119. tab. 214. Jacq. Amer. 278. tab. 169? (Bactris globofa minor; Gært. 1. 22. fig. 9.) "Aculeate-fpinous; trunk fpindle-fhaped; fronds pinnated; ftipes and fpathes fpinous." *Trunk* the thicknefs of the human body, thirty feet high, thick fet with fharp black prickles of different lengths, and placed ufually in rings. *Leaflets* very long and prickly. *Fruit* the fize and fhape of a crab; rind green; pulp thin, fweetifh, aftringent; kernel white, fweet, eatable. Sloane. *Drupe* globular, a little flattened, about an inch in diameter, terminated by three acute feffile ftigmas, protected at the bafe by the permanent calyx and corolla; leaves of the calyx fmall; rind thick, coriaceous; flefh thick, fucculent, at length fungous-coriaceous, adhering to the fhell of the nut; nut globular, fomewhat lenticular, hard as ftone, thick, of a ferruginous bay colour, one-celled; ftamped at the fides with three holes, two of them clofed at the bottom, the third pervious. *Receptacle* none. *Seed* fingle, fomewhat globular, lying horizontally oppofite to the pervious hole of the fhell, flattifh, or flightly depreffed near the hole, reticulated on all fides with arched ftriæ, of a brown bay colour. *Albumen* flefhy, oleaginous, white, fomewhat friable, hollow within. *Embryo* horizontal, oblong, milky white, elongated from a roundifh bafe into a thick oblong lamina. Gært. A native of the Caribbee iflands. Obf. Gærtner feparates the laft two fpecies from cocos, on account of the horizontal pofition of the embryo. Whether fuch a difference in the internal ftructure of the feed be a fufficient generic character, we may doubt, but will not determine.

Cocos *nypa*; Loureiro. See Nipa.

Propagation and Culture. The cocoa-nut tree is fometimes raifed in our ftoves; but it is many years in advancing to any confiderable height; the young leaves, however, being pretty large, they make a good appearance among other tender exotics in two or three years. The nuts muft be imported when they are fully ripe, in a tub filled with dry fand, and carefully fecured from vermin; they will frequently fprout in their paffage, which is an advantage, becaufe they may be immediately planted in pots of earth, and plunged into the hot-bed. As their roots fhoot deeply and widely, they will not bear tranfplanting, unlefs when very young, and even then great caution is requifite to prevent their being injured.

Cocos, in *Geography*, a fmall ifland in the Pacific ocean; uninhabited, but affording anchorage, the beft at the north-eaft extremity, excellent water, wood, fifh, birds, and cocoa-nut trees, whence its name. The anchoring place is by Vancouver's obfervations in N. lat. 5° 35'. E. long. 86° 55'.

Cocos, a group of fmall iflands in the Indian fea, fituated about the diftance of 165 leagues to the S.W. of *Flat* point, the moft fouthern of the ifland of Sumatra. The northernmoft is a fingle low ifland, in S. lat. 11° 50'. E. long. 97° 8'. and lies due N. from the moft weftern of the clufter of iflands, at the diftance of 14 miles. Between them is a fair paffage. The fouthernmoft are a circular range of low iflands, whofe latitude is from 12° 4' to 12° 23' S. Their eaftern extreme 97° 19' E. long.; and their weftern extreme under the meridian of the moft northern iflands.

Cocos, *Cape*, a cape on the eaft coaft of the ifland of Madagafcar. S. lat. 14° 20'. E. long. 55° 58'.

Cocos, in *Natural Hiftory*, a pyritic foffil, found in the cliff of the ifland of Shepey, annexed by fir Jofeph Banks to the collection in the Britifh Mufeum.

COCOSA, in *Ancient Geography*, a place of Gaul, on one of the routes from Aquæ Tarbellicæ to Burdigala.

COCOSATES, a people of Gaul, in Aquitaine.

COCOSSII, a people of Africa, im Mauritania Tingitana. Ptolemy.

COCOTZIN, in *Ornithology*, the name given by Buffon and others to the Indian turtle or ground dove, *columba pafferina*. See Columba.

COCOXIHUITL, in *Botany*, Her. Mex. See Bocconia.

COCROTALEON, in *Natural Hiftory*. Under this name the ancients defcribe a ferocious hybrid brute, generated, as they pretended, between the hyæna and the lionefs. This animal, according to their account, poffeffed many qualities of the mantichora; and as fome believe was only another name for the fame beaft; it was alfo called leucrocotta, and leucrocatta, or fimply crocotta, and cocrotta. We regard the whole hiftory of this creature as fabulous; the production of a hybrid brute engendered between the two animals before-mentioned, is within the limits of poffibility, but their defcription is inadmiffible; they tell us the body refembled that of the lionefs, that the tail was annulated, and the vifage human.

COCTIER, James, or Cottier, as Chaumel calls him, in *Biography*, in his "Effay on the State of Medicine in France," was phyfician to Lewis XI. and obtained fuch influence over the mind of that voluptuous and cruel prince, as to be feared, the hiftorians of the times fay, by him, who was the dread of the reft of the world. Having cured the king of a complaint which had baffled the endeavours of the phyficians and furgeons who had been ufed to attend him, he had the art to get them difmiffed, and to have their places filled by his own creatures, who, finding their patient enfeebled by difeafe, and dreadfully afraid of dying, were unceafing in their commendations of their patron, whom they extolled as the only phyfician capable of prolonging his life. Coctier, on his part, took care to profit by this weaknefs, extorting from him immenfe fums, as the reward for his fervices. On the death of Lewis, in 1483, a commiffion was inftituted to inquire by what means Coctier had acquired his prodigious poffeffions; when it appeared he had received from the king 98,000 crowns within the laft eight months. Coctier, finding he was in danger of lofing the whole of his ill-gotten wealth, had the addrefs to prevail on the king, Charles VIII. to accept 50,000 crowns, and to put an end to the inquiry. Philip de Comines. Eloy. Dict. Hift.

COCTION, a general name for all alterations made in bodies, by the application of fire or heat. See Boiling.

COCUJUS,

COCUJUS, in *Entomology*, the name under which Mouffet deſcribes the inſect vulgarly known by the name of Jamaica fire-fly; it is of the elater genus, and has a large oval lucid, or ſhining yellow ſpot on each ſide of the thorax. Brown, in his "Hiſtory of Jamaica," calls it *elater major fuſcus phoſphoricus*; and tells us, that the lucid ſpots on the thorax are phoſphoreſcent, in which particular, his aſſertion is corroborated by the teſtimony of other writers. This inſect is the *elater noctilucus* of Linnæus.

COCUMONT, in *Geography*, a town of France, in the department of the Lot and Garonne; two leagues S.W. of Marmande.

COCUSUS, or Cucusus, in *Ancient Geography*, a town of Cataonia, upon the Carmalus, near the frontiers of Cilicia, N.E. of Irenopolis.

COCYLIUM, a town of Myſia.

COCYTA, a river of Epirus, which ran near the town of Cichyra, according to Pauſanias.—Alſo a river of Italy, in Campania, near the Lucrine lake, according to Silius Italicus, and Petronius.

Cocyta, in *Entomology*, the *papilio cocyta* of Cramer, is the ſpecies deſcribed by Fabricius, under the name of *papilio morpheus*, which ſee.

COCYTUS, in *Mythology*, one of the rivers of Hell; ſo named from a Greek word κωκυειν, to *lament*; Thus, Milton (Par. Loſt, B. ii.)

> "Cocytus, named from lamentation loud
> Heard on the rueful ſtream."

Cocytus and Phlegethon were branches of the river Styx, which flowed in contrary directions, and afterwards reuniting, augmented the large channel of the Acheron. According to Horace, Cocytus flowed with a dull and languid ſtream. Hence was derived "Cocyta virgo," the appellation of Alecto, one of the Furies.

COD, in *Ichthyology*, a genus of fiſhes, comprehending about twenty different ſpecies. See Gadus.

Cod, *Cape*, in *Geography*, a cape of North America, the ſouth-eaſtern point of Maſſachuſetts' bay, in the ſtate of Maſſachuſetts'. N. lat. 42° 4′. W. long 70° 10′. It probably derives its name from the multitude of cod-fiſh, found on its coaſt. Its form reſembles a man's bended arm, with the hand turned inwards towards the body. The cape comprehends the county of Barnſtaple, though the name "Cape Cod," ſtrictly ſpeaking, ought to be confined. See Barnstaple, and Province-town. What is called "Race-point," known to all ſeamen, is the north-weſterly extremity of the cape, and lies N.W. from Province-town, diſtant three miles. See Race-point. The ſoil of Cape Cod is, in general, more thin and barren than any other part of New England, but the ſea-air impregnates all vegetables with a quality which renders them much more nutritious to cattle than the ſame quantity far inland. The ſalt-hay, which is almoſt their only forage, affords a manure which is ſuperior to that which is procured at a diſtance from the ſea. This greatly aſſiſts their crops of corn and rye. The lands of Cape Cod, however, could never ſupport its inhabitants, which are reckoned to amount to upwards of 18,000. The men and boys are, therefore, for the moſt part, conſtantly employed at ſea; ſo that Cape Cod is an excellent nurſery for ſeamen. The Cape abounds with clear freſh ponds, well ſtocked with fiſh; and formerly the inhabitants took many whales round the Cape; but that buſineſs is almoſt at an end. The manner of taking black-fiſh, which are of the whale kind, about five tons in weight, and yield oil, like the whale, is ſomewhat ſingular. When a ſhoal of them is diſcovered, ſometimes conſiſting of ſeveral hundreds, the inhabitants put off in boats, and getting beyond them, drive them, like a herd of cattle, to the ſhore and flats, where they are left by the tide, and thus become an eaſy prey. The ſhore of the Cape is, in many places, covered with the huge bones of theſe fiſh, and of whales, which remain unconſumed for many years. The wood on the Cape is generally pitch-pine.

It has been conjectured that the Cape is gradually wearing away, and that it will ultimately fall a ſacrifice to the ravages of the winds and ſeas. Many circumſtances ſeem to favour this opinion. At Province-town harbour, ſtumps of trees are ſeen, which are now covered by the ſea in common tides. When the Engliſh firſt ſettled upon the Cape, about the year 1620, there was an iſland off Chatham, at the diſtance of three leagues, called "Webb's iſland," containing 20 acres, covered with red cedar or ſavin. The inhabitants of Nantucket uſed to carry wood from it. This iſland has been wholly worn away for almoſt a century. A large rock, that was upon the iſland, and which ſettled as the earth waſhed away, now marks the place; it riſes as much above the bottom of the ſea, as it uſed to riſe above the ſurface of the ground. On this ſpot the water is ſix fathoms deep, and in many places on the Cape the ſea appears to be encroaching upon the land. The Cape is ſo much expoſed to various winds, that fruit trees do not thrive. The ſituation is healthy, but the piercing winds that proceed from the ſea are trying to delicate conſtitutions. The inhabitants, however, live in general, as long as thoſe of other parts of the northern ſtates. The winds in every direction come from the ſea; and invalids, by viſiting the Cape, ſometimes experience the ſame benefit as from going to ſea.

Cod's *Head*, a cape on the S.W. coaſt of Ireland. N. lat. 51° 36′. W. long. 9° 59.′

Cod-*fiſh*, in *Ichthyology*. See Gadus *morhua*.

Cod-*fiſhery*. See Fishery.

CODA, Benedetto, in *Biography*, a Ferrareſe painter, who was, according to Vaſari, a ſcholar of Giovanni Bellini; he afterwards ſettled in Rimini, where he painted many works, in a ſtyle ſomething leſs dry than thoſe of his maſter. Amongſt his beſt pictures, is the marriage of the Madonna, which is placed in the Duomo, with the inſcription "opus Benedicti," and that of the roſary, at the Dominicans. He died about the year 1520. Benedetto was, however, far ſurpaſſed by his ſon, Bartolommio Coda, of whom there is, at the church of St. Rock, at Peſaro, an altar picture, repreſenting the tutelar ſaint, and St. Sebaſtian, one on each ſide the throne of the Madonna, accompanied by a choir of angels full of grace; it bears date 1528, and is in almoſt every reſpect a performance worthy the golden age in which it was painted. Lanzi. Storia Pitt.

Coda, *Ital.* a tail-piece, addition to, or termination of, a movement in muſic.

Coda *lancea*, in *Ornithology*, the name given by the Italian authors to the *anas caudacuta*, and vulgarly known in England by the names of *cracker*, or *ſea pheaſant*; the *pintail duck* of Engliſh, and *anas acuta* of modern Latin writers. This bird is diſtinguiſhed by having the two middle tail-feathers longer than the reſt, and acute or pointed; the hind head on each ſide marked with a white line, and the back aſh-coloured and undulated. The female is rather ſmaller than the male. It inhabits America, Europe, and Aſia.

CODAGAM, in *Botany*: Rheed. Mal. See Hydrocotyle *aſiatica*.

CODAGA-PALA. Rheed. Mal. See Nerium *antidyſentericum*.

CODANA, in *Ancient Geography*, a place of Aſia, ſituated, according to Ptolemy, on the coaſt of Gedroſia.

CODANONIA, an iſland, placed by Mela in the Codanus Sinus; ſuppoſed to be the iſle of Seeland or Zealand.

CODANUS Sinus, the Baltic ſea, a gulf N. of Germany, between this country and Scandinavia. Mela repreſents it as diverſified with large and ſmall iſlands, inhabited by the Cimbri and Teutones. See Baltic.

CODA-PILAVA, in *Botany*. Rheed. Mal. See Morinda *citrifolia*.

CODARIUM. Solander. Vahl. Claſs and Order, *diandria monogynia*.

Eſſ. Ch. Calyx five-leaved. Corolla one-petalled, linear-lanceolate, inſerted into the ring of the nectary. Legume pediceſled, filled with a farinaceous ſubſtance, generally with a ſingle ſeed, but ſometimes with two or three, valveleſs.

Sp. C. *guineenſe* (dialium guineenſe. Willd.) A tree, or ſhrub. *Branches* cylindrical; bark grey, uneven with chinks and wartlike projections. *Leaves* alternate, unequally pinnated; leaflets five, oblong, quite entire, ending in an obtuſe point, veined; ſmooth and ſhining on the upper ſurface, uneven underneath, with papillæ, which are not viſible without a lens; petioles pubeſcent, tranſverſely wrinkled. *Flowers* numerous, in a very compound panicle, pubeſcent; calyx-leaves coriaceous, pubeſcent on the outſide; upper one broader, oblong, emarginate: the others oblong, acute; filaments two, thick, awl-ſhaped, incurved; anthers two on each filament, connate, oblong; germ ſuperior; ſtyle awl-ſhaped, incurved; ſtigma awl-ſhaped. A native of Guinea.

CODBECK, in *Geography*, a river of England, in the north-riding of Yorkſhire, which paſſes by Thirſk, and joins the Willowbeck, about 2 miles below that town; and about 2 miles after their union they fall into the Swale.

CODDA-PANNA, in *Botany*. Rheed. Mal. See Corypha.

CODDAM-PULLI. Rheed. Mal. See Cambogia.

CODDED *Corn violet*. See Campanula *hybrida*.

CODDY-moddy, in *Ornithology*, the Engliſh name of a ſpecies of gull, very common in the winter ſeaſon on our coaſts; it is the winter-mew of ſome Engliſh authors, and *larus hybernus* of Gmelin; *larus fuſcus ſ. hybernus*, Ray. *Larus canus β cinereus ſubtus niveus, capite albo maculis fuſcis vario, collo ſupra fuſco, alis variis, rectricibus albis faſcia nigra.* Lath. Ind. Orn. It is cinereous, beneath ſnowy white, the head white and varied with brown ſpots, the neck brown, wings ſpotted with brown, and the tail marked with a black band. Suppoſed to be a young bird, of the common gull kind, which has not attained its full ſtate of plumage.

CODE, Codex, a collection of the laws and conſtitutions of the Roman emperors, made by order of Juſtinian.

The word comes from the Latin *codex, a paper book*; ſo called *à codicibus*, or *caudicibus arborum, the trunks of trees*; the bark whereof, being ſtripped off, ſerved the ancients to write their books on.

The code is compriſed in twelve books, and makes the ſecond part of the civil, or Roman law.

There were ſeveral other codes before the time of Juſtinian, all of them collections or abridgements of the Roman laws. The moſt ancient code, or digeſt, was ſtyled "jus Papirianum," from the firſt compiler, Papirius, who flouriſhed about the time of the Regifugium. Mr. Gibbon, however, ſuſpects, that the Caius Papirius, the pontifex maximus, who revived the laws of Numa (Dionyſ. Hal. l. iii. p. 179), left only an oral tradition; and that the "jus Papirianum" of Granius Flaccus, (Pandect. l. 4. tit. xvi. leg. 144.) was not a commentary, but an original work, compiled in the time of Cæſar (Cenſorin. de die natali. l. iii. p. 13. Duker de Latinitate J. C. p. 157.) Gregorius and Hermogenes, or Hermogenianus, two lawyers, who flouriſhed under Conſtantine and his children, made each a collection of this kind, called, from their names, the *Gregorian Code*, and *Hermogenian Code*. The former included the conſtitutions of the emperors from Adrian, or, as ſome ſay, Auguſtus, to Diocleſian and Maximian. This was publiſhed in Schultens's "Juriſprudentia Ant. Juſtitiæ." The latter, which is a ſupplement to the former, was compiled in the age of the Conſtantines, and compriſed all the imperial conſtitutions of Diocleſian and Maximian, beſides thoſe of Claudius, Aurelian, Probus, Caius, and Caginus, to the year 306, or 312. The authors, in compiling theſe, their reſpective works, followed the order of time; which was afterwards obſerved in the codes of Theodoſius and Juſtinian. They were both abridged by thoſe who abridged the Theodoſian code; Gregorius is commonly believed to have been the moſt ancient of the two. The ſtyle of Hermogenianus is very uncouth, and often obſcure.

Cujas aſſigns to Gregory the reigns from Adrian to Gallienus, and the continuation to his fellow-labourer Hermogenes. But though this general diſtribution may be juſt; yet they often treſpaſſed on each other's ground. We have nothing remaining of them but a few fragments in different books of juriſprudence; the compilations themſelves falling to the ground for want of authority to put them in execution.

Theodoſius the Younger was the firſt emperor who made a code, which was compriſed in 16 books, formed out of the conſtitutions of the emperors from Conſtantine the Great to his own time; and compiled by eight able civilians, at the head of whom was Antiochus, who had been conſul in 431; abrogating all other laws not included in it; and this is what we call the Theodoſian code, which was publiſhed in the year 438, and received and obſerved in the eaſt for about 90 years, till annulled by the code of Juſtinian.

The Theodoſian code has been a long time loſt in the Weſt; Cujas took a great deal of pains to retrieve it, and to publiſh it in a better condition than ever. Gothofred has given us a comment on the Theodoſian code; a work which coſt him thirty years.

Theodoſius, in publiſhing the code, enacted, that the laws made by one prince ſhould be of no force in the dominions of the other, unleſs confirmed and ſigned by him.

In 506, Alaric, king of the Goths, made a new collection of the Roman laws, taken from the three former codes, the Gregorian, Hermogenean, and Theodoſian, which he likewiſe publiſhed under the title of the Theodoſian code. This code of Alaric continued a long time in force; and was all the Roman law received into France. It is ſometimes called the code of Anian, becauſe compiled by Anian, who was chancellor to Alaric.

Laſtly, the emperor Juſtinian, finding the authority of the Roman law exceedingly weakened in the Weſt, upon the decline of the empire, made a general collection of the whole Roman juriſprudence. The management hereof he committed to his chancellor, Trebonianus; who choſe out the moſt excellent conſtitutions of the emperors, from Adrian to his own time; and publiſhed his work in 529, under the title of the New Code.

But becauſe Juſtinian had made ſeveral new deciſions, which made ſome alteration in the ancient juriſprudence, he retrenched ſome of the conſtitutions inſerted by Trebonianus, and added his own in their place; on which account he publiſhed a new edition of the code in 534, and abrogated the former. See Civil *Law*.

There have been various other later codes, particularly of the ancient Gothic, and ſince of the French kings; as the code

code of Frederic, the code Michault, code Louis, code Neron, code Henry, code Marchand, code des Eaux, code Noire, &c.

Code *of canons*, *Codex canonum*. See Canon.

CODECEIRO, in *Geography*, a town of Portugal, in the province of Beira; six miles S. from Guarda.

CODEN, a town of America, in the state of Virginia, nine miles S.E. of Cumberland.

CODERA, Cape, a cape of South America, on the N. coast of Terra Firma, in the district of Caraccas. N. lat. 10° 50'. W. long. 66° 21'.

CODESI, a town of European Turkey, in the province of Epire, 16 miles E. of Valona.

CODEX, in *Antiquity*, a kind of punishment by means of a clog, or block of wood, to which slaves, who had offended, were tied fast, and obliged to drag it along with them; and sometimes they sat on it closely bound.

Codex *Argenteus*. See Argenteus *Codex*.

CODIA, in *Botany*, (from κωδια, a *little bail*; the flowers growing in a small head.) Linn. jun. Supp. 33. Schreb. 675. Willd. 783. Forst. Gen. 30. Juss. 430. Class and order, *octandria digynia*.

Gen. Ch. *Cal. common.* Involucre four-leaved, leaves oblong, horizontal. *Cal. proper.* Perianth four-leaved; leaves elliptical, erect. *Cor.* Petals four, linear, with claws. *Stam.* Filaments eight, longer than the corolla, growing two together at the base of each petal. *Pist.* Germ superior, very small, villous; styles two, awl-shaped, the length of the stamens; stigmas simple. *Receptacle common*, villous.

Eff. Ch. Calyx four-leaved Petals four. Common receptacle involucred

Sp. C. *montana.* A shrub. *Leaves* opposite, petioled, elliptical, obtuse, entire, very smooth. *Heads of flowers* globular, peduncled, short, axillary and terminal. *Fruit* unknown. A native of New Caledonia.

CODIÆUM, Rumph. See Croton *Variegatum.*

CODIAVANACU, Rheed. See Tragia *Chamælea.*

CODICIL, a schedule, or supplement to a will, or other writing.

It is used as an addition to a testament, when any thing is omitted which the testator would add, explain, alter, or retract; and is of the same nature as a testament, except that it is without an heir, or executor. So that a codicil is a less solemn will, of one that dies either testate or intestate, without the appointment of an heir; testate, when he that hath made his codicil hath either before or afterwards made his testament, on which that codicil depends, or to which it refers; intestate, when one leaves behind him only a codicil without a testament, wherein he gives legacies only to be paid by the heir at law, and not by any heir instituted by will, or testament.

A codicil, as well as a will, may be either *written*, or *nuncupative*. Some authors call a testament, a *great will;* and a codicil, a *little one*.

But there is this further difference between a codicil and a testament, that a codicil cannot contain the institution of an heir; and that in a codicil, a man is not obliged to observe strictly all the formalities prescribed by law for solemn testaments.

In customary countries, testaments, properly speaking, are no more than codicils; because custom itself names the heir, and does not allow of testamentary inheritors.

Codicils were first brought into use in the time of Augustus, by L. Lentulus; they were originally intended to follow the testament; which was, as it were, their basis. In process of time, codicils came to have their effect, even though made before the testament; provided there was nothing in the testament contrary to the codicil. People were also allowed to make codicils without testaments. Conquest and the formalities of law, says Mr. Gibbon, (Hist. of the Decline and Fall of the Roman Empire, vol. viii. p. 80) established the use of codicils. If a Roman was surprised by death in a remote province of the empire, he addressed a short epistle to his legitimate or testamentary heir; who fulfilled with honour, or neglected with impunity, this last request, which the judges before the age of Augustus were not authorised to enforce. A codicil might be expressed in any mode, or in any language; but the subscription of five witnesses must declare that it was the genuine composition of the author.

Raymond Lully has a book which he calls the "Codicil;" wherein he pretends to have left his readers the secret of the philosophers' stone; provided they do but understand it.

CODINA, in *Geography*, a town of the island of Sardinia, 14 miles E.S.E. of Oristagni.

CODINUS, George, in *Biography*, flourished in the latter part of the fifteenth century. To him, in conjunction with others, was entrusted the care of the palace of Constantinople. He wrote a treatise concerning the origin of that city in the Greek language, and another concerning the officers of the palace, and those of the great church in that city. These works were translated into the Latin, and printed in Greek and Latin at Paris, in 1615.

CODIROSSO, in *Ornithology*, the name under which Olina describes the red-start, *motacilla phœnicurus*. See Motacilla.

Codirosso-*maggiore*, of Olina, is the rock-shrike, *lanius infaustus* of Gmelin, merle de roche of Buffon. See Lanius.

CODIUM, in *Botany*, a genus formed by Stackhouse, for the fucus tomentosus of Linnæus, to which he gives the following character. *Fructification* in small implicated tubes. *Frond* cylindric-compressed; when wet, having the appearance of spunge; when dry, tomentous. See Fucus.

CODLINS and Cream. See Epilobium *Hirsutum.*

CODMA, in *Geography*, a town of Persia, in the province of Segistan, 154 miles S.S.W. of Zareng.

CODOGNO, a town of Italy, in the Lodesan, at the conflux of the Adda and the Po; 12 miles S.S.E. of Lodi.

CODOLAN, Cape, a cape on the E. coast of the island of Formentera, in the Mediterranean.

CODON, in *Antiquity*, a cymbal, or rather little brass bell, resembling the head of a poppy. They were fastened to the trappings and bridles of horses.

Codon is also used to signify the orifice of a trumpet.

Codon, in *Botany*, (from κωδων, a *little bell.*) Linn. Gen. 1285. Syst. Nat. Ed. 13. vol. ii. p. 292. Schreb. 715. Willd. 823. Gært. 596. Juss. 422. Class and order, *decandria monogynia.* Nat. Ord. *undetermined*; Juss. *Borragineæ;* Lam.

Gen. Ch. *Cal.* Perianth one-leafed, deeply ten-cleft; permanent; segments narrow, linear. *Cor.* monopetalous, campanulate, torulose at the base; border ten-cleft, regular; nectary consisting of ten scales, inserted into the base of the stamens, covering the receptacle. *Stam.* Filaments ten, the length of the corolla; anthers thick. *Pist.* Germ superior, conical; style the length of the stamens; stigmas two, long, bristle-shaped, diverging. *Peric.* two-celled. *Seeds* roundish, echinate, bedded in a juiceless coloured pulp.

Eff. Ch. Calyx ten-cleft, permanent. Corolla bell-shaped; border ten-cleft. Nectary composed of ten scales. Pericarp two-celled, containing several seeds.

Sp. C. *Royeni.* Mart. Lam. Willd. (C. aculeatum; Gært. tab. 95. fig. 7.) *Root* annual. *Stem* about a foot high, herbaceous, firm, full of pith, cottony, echinate, with numerous very white prickles, branched. *Leaves* alternate, petioled, egg-ſhaped; clothed on each ſide with a ſhort cottony down, and rough with ſmall hard prickles, ſimilar to thoſe which are found in moſt of the borragineæ; nerves and petioles beſet with white prickles. *Flowers* ſituated a little above the axils of the leaves, ſolitary, rather large; peduncles ſhort, cottony, and like the calyxes, very prickly. Lam. From a ſpecimen ſent to Juſſieu by ſir Joſeph Banks. *Fruit.* capſule, encloſed in the permanent, connivent calyx; ovate-acuminate, terminated by the compreſſed forked ſtyle, marked along both ſides with a ſharp ſuture, ſmooth, two-celled, two-valved; partition contrary to the valves, cloven and ſpongy next the axis. *Seeds* numerous, ſmall, variouſly angular, blood-red, covered on all ſides with ſoft papillæ of the ſame colour. Gært. Native country unknown.

CODORUS, in *Geography*, a townſhip of America, in York county, Pennſylvania.

CODRANA, in *Ancient Geography*, a town of India, on this ſide of the Ganges. Ptolemy.

CODRINGTON, Christopher, in *Biography*, was born at Barbadoes in the year 1688. When he was able to bear the fatigues of the voyage he was ſent to England, and, after ſome continuance at a private ſchool at Enfield, he was removed to Chriſt-church, Oxford. Here he took the degree of maſter of arts, and then was entered as probationer-fellow of All-Souls college, where he completed his ſtudies, and juſtly obtained the character of an accompliſhed gentleman and univerſal ſcholar. Without quitting the fellowſhip of his college, he joined the army, and, through the intereſt of the prince, ſoon attained the rank of captain in the firſt regiment of guards. He was inſtrumental in driving the French out of the iſland of St. Chriſtophers, which they had ſeized at the breaking out of the war between France and England. He diſtinguiſhed himſelf at the ſiege of Namur; and upon the peace of Ryſwick he was made captain-general, and governor of the Leeward Caribbee iſlands. For his conduct in this office he was charged with miſdemeanors, and ſeveral articles of impeachment were exhibited againſt him to the Houſe of Commons in England; to which an anſwer was publiſhed, with atteſtations in his favour, from the lieutenant-governor, members of the council, and the repreſentatives of Nevis. In 1703, he ſhowed the greateſt courage in the attack upon Guadaloupe, though the enterprize failed: this was probably the laſt warlike expedition in which he engaged, and he ſhortly after reſigned his government, and retired to enjoy a literary leiſure. He died in 1710, at his ſeat in Barbadoes, and was at firſt buried in that iſland, but in 1716 his body was removed to England and interred in the chapel of All-Souls, in which two orations were delivered on the occaſion, one by Digby Cotes, univerſity orator, the other by Edward Young, LL. B. By his laſt will he bequeathed a conſiderable eſtate in Barbadoes to the ſociety for the propagation of the Goſpel in foreign parts; he left alſo ten thouſand pounds to the college of All-Souls, for the purpoſe of building a library and the purchaſe of books. Biog. Brit.

CODRIO, in *Ancient Geography*, a ſtrong town of Macedonia, mentioned by Livy, l. xxxi. c. 27.

CODRONCHUS, Baptist, in *Biography*, a learned and intelligent phyſician of Imola in Italy, and author of ſeveral ingenious works on the ſubject of medicine, flouriſhed the latter end of the 16th and beginning of the 17th centuries. That he was much valued, we learn from his correſponding with the moſt eſteemed writers in his time; his works are alſo in the liſt of thoſe recommended by Boerhaave in his "Methodus ſtudii Medici." The titles of the principal of them are, "De chriſtiana et tuta medendi ratione, cum tractatu de baccis orientalibus, (cocculis indicis) et antimonio." Ferraria, 4to. 1591. The Indian berries were uſed as poſſeſſing an intoxicating power to attract or intice fiſh to the hook. They have long been ſuppoſed to be uſed by brewers, to give their beer a power of ſtupefying, without infuſing ſo much malt as would otherwiſe be required. In too large a doſe they would deſtroy life; the uſe of them in brewing is, therefore, very properly prohibited. "De morbis qui Imolæ et alibi communiter, anno 1602, vagati ſunt, commentarius, in quo potiſſimum de lumbricis tractatur, et de morbo novo, prolapſu nempe cartilaginis mucronatæ." Bononiæ, 1603, 4to. In this complaint, which appears to have been a fever, the patients were not relieved until after diſcharging a kind of worm, which the author deſcribes as differing from thoſe commonly found in the inteſtines. The author wrote alſo on the effects of different kinds of poiſons, and the remedies for each kind, and the diſeaſes occaſioned by witchcraft, in which he appears to have had great faith: On hoarſeneſs and other affections of the voice, and on the method of giving evidence in courts of juſtice: On the hydrophobia, of which he had ſeen ſome inſtances, and on the adminiſtering of hellebore, which he highly commends as a cathartic. Haller Bib. Med. Eloy. Dict. Hiſt.

CODROPIO, in *Geography*, a town of Italy, belonging to the ſtate of Venice, in the country of Friuli; 10 miles S.S.W. of Udina.

CODROPOLIS, in *Ancient Geography*, a town of Illyria, ſituated at the lower part of the Adriatic ſea, and ſerving as a boundary to the empire, divided between Auguſtus and Marc Antony.

COD-ROY, in *Geography*, a river of Newfoundland, which runs into the ſea, between cape Ray and cape Anguille.

CODRUS, in *Biography*, the 17th and laſt king of Athens, is celebrated for the noble act of ſacrificing his life for his country. He was the ſon of Melanthus, and had reigned twenty years, when the Heraclidæ made war againſt Athens. On this occaſion the Delphic oracle was conſulted, who declared that victory would decide for that people whoſe ſovereign was ſlain in battle. The enemy gave ſtrict charge to ſpare the life of Codrus, but the monarch, reſolving to enrol his name among the benefactors of his people, diſguiſed himſelf as a peaſant, and was ſlain in combat. When this was known to the Heraclidæ, they, dreading the accompliſhment of the prediction, broke up the camp and retreated. From this period, the Athenians regarded Codrus as the father of his country, and to pay the higheſt poſſible regard to his memory, they reſolved that no man was fit to reign as king after him; the monarchy was accordingly aboliſhed, and the government placed in the hands of elective magiſtrates, entitled archons, of whom the firſt was Medon, ſon of Codrus, who ſuſtained the office 20 years. This event took place about 1070 years before the Chriſtian æra. Juſtin. Univer. Hiſt. Du Freſnoy.

CODUTÆ, or Cudutæ, in *Ancient Geography*, a people of India, on the other ſide of the Ganges. Ptolemy.

CŒCILA, a town of Spain, placed by Ptolemy in Bœotia, in the country of the Turduli.

CŒCILIANA, a place on the river Calipos, E. of Cetobriga, and S.E. of Uliſipo.

CŒCINUM, a town of Italy, on the eaſtern coaſt of Brutium.

CŒCINUS,

CŒCINUS, a ſmall river which watered the town of Cœcinum, and diſcharged itſelf into the ſea to the eaſt.

CŒCK, Pieter, in *Biography*, called likewiſe *P. Van Aelſt*, from the place of his nativity, a town in Flanders, was, if we can form any judgment from the writers who have ſpoken of him, or from the admirable prints remaining from his deſigns, one of the greateſt painters which either Germany or Flanders produced in his time. After he had been ſometime inſtructed in the ſchool of Bernard of Bruſſels, he went to Rome to complete his ſtudies, and ſoon proved himſelf an excellent deſigner, and a bold and ſpirited painter, as well in freſco as in oil. At his return to his own country he married, but his wife ſoon dying, he once more gave way to his natural inclination for travelling, and at the ſolicitations of a merchant, a friend of his, accompanied him to Conſtantinople in the year 1531.

Having ſtaid ſome time with the Turks, and drawn ſome moſt animated repreſentations of their cuſtoms and ceremonies, which he afterwards cut in wood, he once more arrived in the place of his nativity, and took a ſecond wife. Towards the latter part of his life he wrote ſome excellent treatiſes upon geometry, architecture, and perſpective. His pictures of hiſtory, as well as his portraits, were much eſteemed. He was made painter to the emperor Charles V. and died at Antwerp, in the year 1550. After his death the prints which he had made of Turkiſh coſtume were publiſhed by his widow. This admirable work conſiſts of ſeven large pieces, which, when joined together, form a frieze, divided into compartments by Cariaticles: on a tablet in the firſt block is written in old French, "Les mœurs et fachom de faire de turez, avecq les regions y appertenantes, ont eſt au vif contrefaicetze par Pierre Cœck d'Aloſt, luy eſtant en Turque, l'an de Jeſu Chriſt, MDXXXIII. lequel auſſy de ſa main propre a pourtraict ces figures duyſantes a l'impreſſion dy'celles;" and on the laſt is this inſcription, "Marie ver hulſt, vefue du dict Pierre d'Aloſt, tres paſſe en l'an MDL. a faict imprimer les dict figures, ſoubz grace et privilege d'l'imperialle majeſte en l'an MCCCCCLIII." Theſe prints are very rare. Baldinucci. Strutt.

CŒCUM, in *Anatomy*, the firſt portion of the large inteſtine, in which the ſmall inteſtine ends. As its dimenſions exceed thoſe of the reſt of the canal, it is alſo known by the name of *caput coli*. See Intestine.

CŒDAMUSII, in *Ancient Geography*, a people of Africa, mentioned by Ptolemy, who inhabited the environs of the town of Sitiphæ, and of the river Ampſagas, in Mauritania Cæſarienſis.

CO-EFFICIENTS, in *Algebra*, are numbers, or given quantities, prefixed to letters, or unknown quantities, into which they are ſuppoſed to be multiplied; and therefore, with ſuch letters, or with the quantities repreſented by them, making a product or co-efficient production; whence the name, firſt given by Vieta.

Thus, in $3a$, or bx, or cxx; 3 is the co-efficient of $3a$; b, of bx; and c, of cxx. If a letter have no number prefixed, it is always ſuppoſed to have unit for the co-efficient. Thus, a, or bc, import as much as $1a$, or $1bc$.

In any equation whoſe higheſt power or term has 1 for its co-efficient, the co-efficient of the ſecond term is always the aggregate of all the roots retaining their proper ſigns; ſo that if all the negatives be equal to all the affirmatives, the ſecond term will vaniſh; and where the ſecond term is thus wanting, it is a ſign that the quantities under contrary ſigns were thus equal.

The co-efficient of the third term is the aggregate of all the rectangles or products ariſing by the multiplication of every two of the roots, how many ways ſoever thoſe combinations of duals can be had; as once in a quadratic, three times in a cubic, ſix times in a biquadratic equation, &c.

The co-efficient of the fourth term is the aggregate of all the ſolids made by the continual multiplication of every three of the roots, how often ſoever ſuch a ternary can be had; as once in a cubic, four times in a biquadratic, ten times in an equation of five dimenſions, &c. And thus it will go on infinitely.

Co-efficients *of the ſame order*, is a term ſometimes uſed for the co-efficients prefixed to the ſame unknown quantities, in different equations.

Thus, in the equations $\left\{\begin{matrix} ax+by+cz=m \\ dx+ey+fz=n \\ gx+hy+kz=p \end{matrix}\right\}$ the co-efficients a, d, g, are of the ſame order, being the co-efficients of x; alſo b, e, h, are of the ſame order, being the co-efficients of y, &c. The co-efficients alſo that affect no unknown quantity, are ſaid to be of the ſame order.

Co-efficients, *oppoſite*, ſuch as are taken each from a different equation, and from a different order of co-efficients. Thus, in the foregoing equations, a, e, k, and a, h, f, as alſo d, b, k, are oppoſite co-efficients.

COEHORN, in *Gunnery*. See Mortars, under the article Cannon.

COEL, in *Geography*, a town of Hindooſtan, in the country of Delhi, 65 miles S.E. of Delhi, and 33 N. of Agra. N. lat. 27° 48'. E. long. 78° 27'.

COELA, in *Ancient Geography*, the name of a part of the Elide, a country of Peloponneſus, according to Pauſanias and Strabo.—Alſo, a town ſituated on the ſtrait of the Helleſpont, S. of Seſtos, and at the lower part of the creek, or ſmall bay in the Thracian Cherſoneſus, whence it took its name "Portus Coelos." Pomponius Mela ſays, that the port of Coela is famous on account of the victory which the Athenians obtained here over the Lacedæmonians, whoſe fleet was utterly deſtroyed. The town of Coela, advantageouſly ſeated both for navigation and commerce, acquired, under Adrian, the privileges and dignity of a municipium; and it was recogniſed under the appellation of "Ælium," from his proper name. After the diſmemberment of the greater provinces of the empire, it became a part of the province of Thrace, called "Europe," under the metropolis of Heraclea.

Coela *of Eubœa*, a place of Greece in the iſland of Eubœa, denoting the ſpace or diſtrict which lay between Aulide and Gereſte.

COELÆ, a ſmall iſland ſituated before the town of Smyrna, on the coaſt of Aſia Minor. Pliny.

COELALETÆ, a people of Thrace, mentioned by Tacitus, and diſtinguiſhed by Pliny into the greater and leſs, and called Cœlatæ. He places the former at the foot of mount Hæmus, and the latter at the foot of mount Rhodope.

COELERINI, a people of Hiſpania Tarragonenſis. Pliny and Ptolemy.

COELESTIAL, in a general ſenſe, denotes any thing belonging to *cœlum* or the heavens. Thus,

Coelestial *obſervations*, are obſervations of the phenomena of the heavenly bodies, made with a proper apparatus of aſtronomical inſtruments, in order to determine their places, motions, phaſes, &c.

Obſervations in the day-time are eaſy; becauſe the croſs hairs in the focus of the object-glaſs of the teleſcope are then diſtinctly perceivable; in the night, thoſe croſs hairs are to be illumined to make them viſible. This illumination is either performed by a candle, placed obliquely near them, ſo that the ſmoke does not intercept the rays; or, where this is inconvenient, by making an aperture in the tube of the teleſcope,

telescope, near the focus of the object-glass, through which a candle is applied to illumine the cross hairs. M. De la Hire has made an improvement on the first method. which renders it of very good use; and it is by covering that end of the tube next to the object-glass with a piece of gause, or fine white silken crape. For, in such case, a link, placed at a good distance from the tube, so enlightens the gause, as to render the cross hairs very perceivable.

Observations of the sun are not to be made without placing a glass, smoked in the flame of a lamp or candle, between the telescope and the eye; to take off from its lustre, which would otherwise damage the eye, were not a good part of its beams intercepted.

Coelestial observations are chiefly of two kinds; the one when the objects are in the meridian; the other, when they are in vertical circles. For an account of the instruments with which observations are made, see our articles CIRCLE, and OBSERVATORY.

COELESTIAL *globe*. See GLOBE.

COELESTIAL *Sphere*. See SPHERE.

COELESTINE. The native sulphat of strontian, called coelestine, from the blueish tint which it generally assumes, is divided into three varieties, the foliated, fibrous, and compact.

1. Foliated. Its colour is milk-white passing into blue. It occurs in mass, or crystallized in strait rhomboidal prisms, or cuneiform octohedrons, or short hexahedral prisms. Its lustre is glittering or shining. Its fracture is imperfectly foliated. It is semitransparent, rarely transparent. It is somewhat softer than flour spar, and is easily frangible. Sp. Gr. 3.5.

It consists, according to Vauquelin, of

54	Strontian.
46	Sulphuric acid.
100	

It occurs in the neighbourhood of Bristol in loose nodules, and very finely crystallized in Sicily.

2. Fibrous. Its colour is between indigo blue and blueish-grey, passing into milk-white; by long keeping it loses its colour. It occurs in mass and in plates. Its longitudinal fracture is curved-fibrous approaching to foliated, with a shining lustre; its cross fracture is splintery, with a glittering pearly lustre. It is translucent, somewhat softer than the preceding variety, and easily frangible. Sp. Gr. 3.83.

It consists, according to an analysis by Klaproth, of

58	Strontian.
42	Sulphuric acid, with a trace of iron.
100	

It occurs in ferruginous marl in the vicinity of Bristol, and at Frankstown in Pennsylvania.

3. Compact. Its colour is blueish or yellowish-grey. It occurs in mass, and in flattened spheroidal and kidney-shaped masses. Its fracture is fine-splintery, passing into foliated. It is opake, and sometimes translucent on the edges. It is soft and easily frangible. Sp. Gr. 3.59.

According to Vauquelin it consists of

91.42	Sulphat of strontian.
8.33	Carbonat of lime.
0.25	Oxyd of iron.
100.	

It occurs imbedded in clay in the gypsum quarries of Mont Mortre, near Paris.

COELESTIS DEA, in *Ancient Mythology*, the *heavenly goddess*, a deity worshipped in Africa, and supposed to be the same with the Mithra of the Persians, and Astarte of the Phœnicians. It had a splendid temple at Carthage, dedicated by one Aurelius, a Pagan high-priest, and destroyed by another Aurelius, created bishop of Carthage, A. D. 390, who converted the Pagan temple into a Christian church, and placed his episcopal chair on the spot where the statue of the goddess had stood. At Rome, on the base of a stone on which the statue of this deity was placed, is found this inscription, "Invictæ Coelesti."

CŒLE-SYRIA, or COELO-SYRIA, in *Ancient Geography*, lay, according to Strabo, between the two mountains Libanus and Antilibanus, and was thence called *Cœle-Syria*, or the Hollow Syria. The cities and towns in this part of Syria, were, according to Ptolemy, Heliopolis, Abila Lysaniæ, Gaana, Ina, Damascus, Samulis, Abida, Hippus, Capitolias, Adra, Scythopolis, Gerasa, Pella, Dium, Gadora, Philadelphia, and Canatha; to which some add Laodicea Cabiosa, or ad Libanum. According to Galen, this country produced black inflammable stones, probably a species of surturbrand or bituminized wood, similar to the Bovey-coal of England; these, he says, were generated in the hills on the east side of the Dead sea, where the bitumen is produced, and had a scent similar to bitumen.

COELIA, Κοιλια, or Κοιλη, in *Anatomy*. This has many different significations; first, it imports a cavity in any part of the body, or in any of the viscera; secondly, it implies the same as *alvus*. The κοιλη, with the addition of ανω, that is, ἡ κατω κοιλη, is the lower belly, or intestinal tube

COELIACA ARTERIA, a large artery derived from the trunk of the aorta, soon after that vessel has entered the abdomen, and distributed to the stomach and duodenum, the liver, spleen, and pancreas. See ARTERIES.

COELIACA *ganglia*, are the nervous ganglia found in the coeliac plexus. See the description of the great sympathetic nerve in the article NERVE.

COELIACA, or the *Cœliac passion*, in *Medicine*, a term used by the older writers, to denote a diarrhœa, in which the stools were of a white appearance, resembling, or consisting of chyle. A distinction was made between this disease and the lientery; inasmuch as the food passed off in an undigested state in the latter; whilst in the cœliac passion the stomach completed the act of digestion, but the chyle, produced by this function, not being absorbed by the lacteals, was discharged by stool. This species of diarrhœa rarely, if ever, occurs; since, where the glands and absorbents of the mesentery, or the intestines themselves, are considerably diseased, the stomach is generally enfeebled in its functions, by sympathy. See DIARRHOEA, and LIENTERY.

COELIACUS *plexus*, in *Anatomy*, is a most intricate nervous network, formed chiefly by the splanchnic nerves, and some branches of the par vagum; consisting of several ganglia, which vary considerably in number, form, size, and position, and are connected to each other by larger and smaller nervous chords; and surrounding the root of the coeliac artery. See NERVE.

CŒLIANUM, in *Ancient Geography*, a place of Lucania, on the route which led from Opinum to Heraclea.

COELICOLÆ, in *Ecclesiastical History*, a sect called also "Hypsistarii," which arose about A. D. 300, or somewhat sooner. They are mentioned in the Theodosian code, as heretics; and seem to have been persons who, rejecting idolatry and polytheism, and all revealed religions, admitted only natural religion. See Wetstein's Proleg. in N. T. p. 38.

COELICOLOR, in *Natural History*, a name given by some to the OPAL.

COELIOBRIGA, in *Ancient Geography*, a place upon the Nebis, in the country of the Callaici, W. of Bracara Augusta.

COELIUS *Mons*, one of the seven mountains or hills of the city of Rome, which owes its name to Coelius, or Coeles, a famous Tuscan general, who pitched his tents there, when he came to the assistance of Romulus, against the Sabines. Livy (l. i. c. 30.) and Dionysius Halicarnassensis (l. iii.) attribute the inclosure of it to Tullus Hostilius; but Strabo (l. v.) to Ancus Martius. The other names by which it was sometimes known, were Querculanus, or Quercitulanus, and Augustus: the first, occasioned by the abundance of oaks growing there: the other imposed by Tiberius, when he had erected new buildings upon it after a fire which consumed the whole of this quarter of the city. (Tacit. Annal. L. Suet. in Tiber. c. 48.) One part of this hill was called "Coeliolus," and "Minor Coelius." To the east it had the city walls; to the south "Mons Aventinus;" to the west, "Mons Palatinus;" to the north, "Mons Esquilinus." Its compass was about 2½ miles.

COELLO, Alonzo Sanchez, in *Biography*, a Portuguese painter, was born in 1526: after having studied some time in Rome, he visited Spain, where he profited from the instruction of Antonio Moro: (sir Antony More): from Spain he passed into Portugal, and was employed by don Juan, and afterwards by donna Juanna, his widow, sister to Philip II. of Spain. About this time, Antonio Moro, in consequence of an indiscretion he had been guilty of, found it advisable to retire from the court of Spain; and Philip solicited his sister to send Coello to occupy his place; on his arrival at Madrid he was treated by that monarch with every mark of respect and condescension, and several times employed to paint the portrait of Philip, on foot, and on horseback, as well as those of the nobles of his court. There are several altar-pieces by Coello in the Escurial, and two of his pictures, representing Sisiphus and Titius, in the royal palace of Madrid; but his greatest composition is the martyrdom of St. Sebastian, in the church of San Geronimo in that city; on the right of the saint stands the figure of Christ, on the left that of the Madonna, and below them San Bernardo and San Francesco; the figure of the Almighty, enveloped in glory, forms the top of the picture. This, like his other works, is executed with great boldness of design and expression, and a style of colouring nearly resembling that of the great Titian. This artist, who certainly ranks amongst the first of the Spanish school of that period, died in the sixty-fifth year of his age in 1590. Cumberland.

Coello, Claudio, of the same family with the abovementioned artist, was born in Madrid in the seventeenth century, but in what year is not known. He became the favourite disciple of Francesco Ricci, painter to Philip III. and through his means gained access to the royal collection, where he assiduously copied many of the finest works of Titian, Rubens, Vandyke, and other masters. With these advantages, and these alone, for he never was out of Spain, Coello became, in the opinion of many, the greatest painter of the school, and decidedly holds a place in the first class. There is a Nativity by this master in the royal palace at Madrid, which, although hanging in the same room with the Adoration of Rubens, loses nothing by the comparison. But his chef d'œuvre is the picture "de las Colocazion de las Santas Formas," which hangs at the altar of the grand Sacristy of St. Lorenzo in the Escurial; this piece is executed in so masterly a style, with so striking an effect of chiaroscuro, and so much harmony, that the eye of the spectator is immediately attracted by it, although it is surrounded by many of the works of Raphael, Titian, and others, of the Italian and Flemish masters; the portraits of the king and the principal nobility are introduced in the great group of the procession, without any wise disturbing the order or solemnity of the whole. The artist was seven years in completing this admirable composition; after which he returned to Madrid, in the year 1689, and was liberally rewarded. It is much to be regretted, that many of Coello's works, in the churches and convents of Madrid, Toledo, and Saragossa, are placed in such bad lights and injudicious situations, as not to appear to that advantage which they so deservedly merit.

His style is said to resemble that of Paul Veronese, particularly in his draperies, colouring, and characters; nor does he fall short of him in magnificence of composition.

His death, which happened in 1693, was, it is supposed, accelerated by the mortification he felt, upon Luca Giordano's being sent for by Charles II., to paint the frescos of the great staircase of the Escurial. Cumberland.

COELMANS, James, an engraver of Antwerp, where he was born in 1670. His chief work consists of some prints, executed by him entirely with the graver, about 1709, from the collection of pictures belonging to M. de Boyer, Comte d'Aguilles, at Aix in Provence; but we cannot say much for his style in general, as it is too dark, heavy, and inharmonious, and by no means correct in point of drawing. Amongst the best of his engravings, for the above mentioned work, are, "The Murder of the Innocents," from Claude Spierre, and "The Fall of the Giants, with Victory crowning David," from Nicolo Poussin. His death happened in the year 1735. Strutt. Heinecken.

COELOMA, in *Surgery*, a hollow and round ulcer, in the horny tunic of the eye.

COELOS, in *Ancient Geography*, a town and port of the sea of the Thracian Chersonesus, between Elæa and Cardia, according to Pliny. It is called "Cœla" by Ammianus Marcellinus. See Cœla.

COELOSSA, or Coelusa, a mountain of the Peloponnesus, in the Argolide, according to Strabo. The Carnæate mountain formed a part of it.

COELUM. See Heaven.

Coelum is also used by some anatomists for the cavity of the eye towards the angles, or *canthi*. See Eye, Canthus, &c.

COELUS, in *Mythology*, one of the heathen deities, the same with the Greek *Uranus*.

COEMETERIUM. See Cemetery.

COEMPTION, among the *Romans*, a rite of marriage, practised on the part of the bride, which, when she was bought by the husband of her parents, she fulfilled by purchasing, with three pieces of copper, a just introduction to his house and houshold deities.

COEMPTIONALES, among the Romans, an appellation given to old slaves, which were sold in a lot with others, because they could not be sold alone.

COEN, John Pieterzoon, in *Biography*, was born in 1587, at Hoorn, in the United Provinces. He was sent to Rome at an early age, to be instructed in trade and commerce, under Piscatore, a celebrated merchant there. In 1607, he went to India; and in 1613, the whole management of the India trade was devolved on him, under the title of "director general," an office which seems to have been made for him. He was chosen president of Bantam, where he fixed his residence, and had great powers entrusted to him. There a plot was laid to assassinate him, which, though it miscarried, led him to the resolution of changing his

his abode. In consequence of this, the Dutch, in the year 1619, took possession of Batavia, where they established the seat of their commerce. For several years the Dutch had to contend with the native king of the place, assisted by the English. Peace was at length concluded between the two companies. The English re-embarked, and Coen laid the foundation of a new city, the streets of which were laid out in straight lines, and so spacious as to admit of canals of water, bordered by trees, that they might afford a shade to those who passed backwards and forwards in boats. The place was fortified, and put into a state of defence, and then it was declared the capital of the Dutch settlements in India. In the year 1622, Coen obtained leave to return to Europe, and in the following January he set sail with five ships, richly laden, and arrived at Zealand in December, having held the supreme command in India for more than four years. In 1627, he proceeded to India again, but he had not been long at Batavia, before the emperor of Java, jealous of the Dutch power, endeavoured to drive them from the island. Twice he laid siege to this city, but so many of the Javanese were killed by the artillery of the besieged, that a contagious distemper broke out among them, to which great numbers fell a sacrifice. It extended even to the Dutch camp and city, and destroyed many of the inhabitants. The Javanese were forced, ultimately, to raise the siege; exasperated with the defeat, they attempted to assassinate Coen. With this view, they sent to Batavia several small vessels laden with provisions, having some armed men concealed in the bottom of them below bamboos. They proceeded to the market-place, where the conspirators hoped to accomplish their purpose, but Coen was too strongly guarded for them to venture upon an attack. He died in September, 1629. Gen. Dict. Univer. Hist.

COENA *domini, bull.* See BULL.

COENA *Triumphalis*, in *Military Language*. When a victorious general made his triumphal entry, it was customary for him to give a banquet or entertainment to the Roman people.

CŒNAKER, in *Geography*, a town of the island of Ceylon, near the south coast; 100 miles S. of Candy.

COENDOU, in *Zoology*, the French name of the Brasilian porcupine, *Hystrix prehensilis.*

CŒNE, or COENOPOLIS, in *Ancient Geography*. See CÆNE.

CŒNENUM, a town, placed by Ptolemy in the northern part of Germany.

COENNERN, or KONNERN, in *Geography*, a town of Germany, in the circle of Lower Saxony, and duchy of Magdeburg, containing about 333 houses; 38 miles S. of Magdeburg.

CŒNOBITE, in *Ecclesiastical History*, formed of κοινος, *common*, βιος, *life*, a religious, who lives in a convent, or in community, under a certain rule; in opposition to *anachoret*, or *hermit*, who lives in solitude.

Cassian makes this difference between a *convent* and a *monastery*, that the latter may be applied to the residence of a single religious, or recluse; whereas the *convent* implies *cœ*-[illegible] living in common.

[illegible] of three kinds of monks in Egypt; [illegible] who continue to live in community; and *sarabaites*, who are a kind of monks errant, that stroll from place to place. (See MONK.) He refers the institution of cœnobites to the times of the apostles, and makes it a kind of imitation of the ordinary lives of the faithful at Jerusalem. Though St. Pachomius is commonly owned the institutor of the *cœnobite* life; as being the first who gave a rule to any community.

COENOBIUM, the state of living in a society or community, where all things are in common. Pythagoras is thought to be the author, or first institutor of this kind of life; his disciples, though some hundreds in number, being obliged all to give up their private estates, in order to be annexed to the joint stock of the whole. The Essenians among the Jews, and Platonists, are said to have lived in the same manner. Many of the Christians also have thought this the most perfect kind of society, as being that in which Christ and his apostles chose to live. See COENOBITE.

COENOTAPH. See CENOTAPH.

COENSIS CIVITAS, in *Ancient Geography*, the same with Cos, the capital of an island of the same name, which was an episcopal see.

COENYRÆ, a place in the island of Tasos, between which, and that called Ænyræ, or Annyræ, there were very rich mines.

CO-EQUALITY, a term expressing the relation of equality between two things.

The retainers to St. Athanasius's doctrine of the Trinity hold the Son and Holy Spirit *co-equal* with the Father. The Arians, &c. deny the *co-equality*. See TRINITY and ARIAN.

COEQUOSA, in *Ancient Geography*, a town of Gaul in Aquitaine, placed by the Itinerary of Antonine on the route from Aquæ Tarbellicæ to Burdigala.

COERULEUM MONTANUM. See COPPER, *ores of*.

COERULEUM *nativum*. See ARMENIUS *lapis*.

COES, among *Miners*, are little houses which the miners make over their mines to lay ore in.

COESCOES, in *Zoology*, the Surinam opossum, *Didelphis orientalis*, is described by Valentine under this name.

COESFIELD, in *Geography*, a town of Germany, in the circle of Westphalia, and bishopric of Munster, the ordinary residence of the bishop, containing two parish churches and five convents; 14 miles W. of Munster.

COESNON, a river of France, which runs into the sea, between Pontorson and Mont St. Michael.

COESTOBOCI, in *Ancient Geography*, a people of European Sarmatia, according to Ptolemy.

CO-ETERNITY is used among *Divines* to denote the eternity of one being equal to that of another. The orthodox hold the second and third persons in the Trinity *co-eternal* with the first.

COETI, in *Ancient Geography*, a people of Asia, in the vicinity of the Tibareni and of the river Thermodon.

COEUR, JACQUES, in *Biography*, a celebrated French merchant, and administrator of the finances under Charles VII. Of such consequence were his commercial pursuits, that he is said to have had 300 clerks in the ports of the east, and that he became the richest individual in Europe. His liberality was as extensive as his wealth was great, and he advanced very considerable sums to his sovereign, to enable him to recover his dominions from the English; in return for this generosity, he was raised to the highest offices of state, and was employed on many important embassies; in these his own wealth was made use of to enhance the glory of his country. His good fortune excited the jealousy of his contemporaries, who exhibited against him many heavy charges, from most of which he readily cleared himself, but he was convicted, by a partial tribunal, of others, and was condemned to pay an enormous fine; his estates were confiscated, and he himself was confined to the convent of Cordeliers at Beaucaire, from whence he escaped to Rome. His subsequent history is involved in obscurity, but it is generally believed that he embarked in an expedition

expedition fitted out againſt the Turks by pope Callixtus III. and died at the iſle of Chio in 1456. Nouv. Dict. Hiſt.

COEUR, in *Heraldry.—Party en* COEUR, ſignifies a ſhort line of partition in pale, in the centre of the eſcutcheon, which extends but a little way, much ſhort of top and bottom; being met by other lines, which form an irregular partition of the eſcutcheon.

COEUS, in *Ancient Geography*, a river of the Peloponneſus, in Meſſenia, which watered the town of Electra, according to Pauſanias.

COEUVRES, or ESTREES, in *Geography*, a town of France, in the department of the Aiſne, and diſtrict of Soiſſons; 7 miles S.W. of it.

CO-EXISTENCE, a term of relation, denoting two or more things to exiſt together at the ſame time, &c. See EXISTENCE.

COEYMANS, in *Geography*, a townſhip of America, in the ſtate of New York and county of Albany; 12 miles below Albany.

COFFEA, in *Botany*, (its true name, according to Bruce, is *Caffé*, from Caffa, the ſouth province of Narea, in Africa, where it grows ſpontaneouſly in great abundance), Linn. Gen. 230. Schreb. 314. Willd. 353. Gært. 139. Juſſ. 204. Vent. 2. 583. (Caffeyer, Encyc.) Claſs and order, *pentandria monogynia*. Nat. Ord. *Stillatæ*, Linn. *Rubiaceæ*, Juſſ. Vent.

Gen. Ch. *Cal.* Perianth ſuperior, very ſmall; four, five, or ſix-toothed. *Cor.* monopetalous, ſalver or funnel-ſhaped; tube cylindrical, ſlender, much longer than the calyx; border longer than the tube, four, five, or ſix-cleft; ſegments lanceolate, expanding, or obliquely reflexed. *Stam.* Filaments four or five, inſerted into the tube of the corolla; anthers linear. *Piſt.* Germ inferior; ſtyle ſimple, the length of the corolla; ſtigmas two, awl-ſhaped, reflexed. *Peric.* Berry roundiſh, about the ſize of a cherry, umbilicated at its ſummit. *Seeds* one or two, elliptically hemiſpherical, gibbous on one ſide, flat and furrowed longitudinally on the other, involved in an aril.

Eſſ. Ch. Corolla ſalver or funnel-ſhaped. Stamens inſerted into the tube. Berry inferior, one or two-ſeeded. Seeds arilled.

Sp. 1. C. *arabica*, Arabian coffee-tree. Linn. Sp. Pl. 1. Mart. 1. Lam. 1. Willd. 4. Lam. Ill. tab. 160. fig. 1. Woodv. Med. Bot. tab. 230. Gært. tab. 25. (Jaſminum arabicum, Juſſ. Act. 1713. p. 388. tab. 7. Till. Piſ. 87. tab. 32. Evonymo. ſimilis œgyptiaca, Bauh. Pin. 428. Bon five ban, Alp. Ægyp. tab. 36. Pluk. Almag. 69. tab. 272. fig. 1.) "Flowers five-cleft; berries with two ſeeds." Linn. "Leaves oblong-acuminate; peduncles axillary, aggregate; corollas five-cleft." Willd. An evergreen ſhrub, from fifteen to twenty feet high. *Trunk* erect, not more than two or three inches in diameter; branches brachiate, two growing at every joint, almoſt cylindrical, flexible, looſe, expanding; lower ones extending horizontally, generally ſimple. *Leaves* four or five inches long, two inches broad, oppoſite, ſimple, ovate-lanceolate, acuminate, quite entire, ſmooth, green, ſhining on the upper ſurface, pale green underneath, on very ſhort petioles. *Stipules* two at each knot of the branch, awl-ſhaped, enlarged at the baſe, oppoſite, intrafoliaceous. *Flowers* white, ſeſſile, axillary, cluſtered four or five together, ſweet-ſcented, ſoon falling off. *Berries* oval-globular, of a dark red colour when fully ripe. Lam. *Berry* inferior, elliptic-ſphæroidal, with a little circular area at the ſummit, having within it a callous point; two-celled, containing a fleſhy, ſomewhat gelatinous pulp; partition vaſcular-fleſhy. *Seeds* one in each cell, elliptical, convex on one ſide, flattiſh, with a longitudinal chink on the other, of a pale glaucous colour; aril of a ſubſtance reſembling paper, elaſtic, pellucid, looſely ſurrounding the ſeed, and entirely covering it. Gært. A native of the old continent and adjacent iſlands, between or near the tropics. 2. C. *mauritiana*. Lam. 2. Illuſ. tab. 160. fig. 2. (C. arabica β. Willd.) "Berries oblong, acute at the baſe; ſeeds two." Lam. *Branches* compound; branchlets oppoſite. *Leaves* only two inches and a half long, ſomewhat acute, but not acuminate, narrowed to a point at the baſe, ſcarcely petioled, ſmooth, much veined. *Berries* axillary, almoſt ſeſſile, never globular, but oblong and narrowed to a point at their baſe, two-celled. *Seeds* one in each cell, oblong, cartilaginous, pointed at one end, not having much thickneſs. Deſcribed by La Marck from a ſpecimen without flowers ſent to Juſſieu. It is evidently nearly allied to the preceding, but eſteemed by La Marck to be ſpecifically diſtinct, on account of the different ſhape of the fruit. This eminent botaniſt has, however, been unaccountably negligent with reſpect to their ſpecific characters, having retained, without addition, that formed by Linnæus for C. arabica, which, in the Species Plantarum, is oppoſed only to C. occidentalis, and by no means excludes any part of the ſpecific character given by La Marck to his C. mauritiana. The following ones will, we believe, ſufficiently diſcriminate them from each other, and from all the ſucceeding ſpecies. C. *arabica*. "Flowers five-cleft; peduncles axillary, cluſtered; leaves acuminate; berries nearly globular; two-celled, with two ſeeds." C. *mauritiana*. "Peduncles axillary, generally ſolitary; leaves ſomewhat acute; berries oblong, leſſened to a point at their baſe, two-celled, with two ſeeds." But after all, it may be doubted whether the ſuperior plumpneſs of the berries of the Arabian coffee may not be entirely the effect of cultivation. A native of the iſle of Bourbon. La Marck, when he wrote the article in the Encyclopedie, did not know whether the coffee, imported into France by the name of caffé de Bourbon, is the produce of the indigenous tree, or of cultivated plants brought originally from Arabia. It has ſince been aſcertained, that the Bourbon coffee is obtained from Arabian plants ſent from Mocha in the year 1717. And we learn from the Memoirs of the Academy of Sciences at Paris for the year 1715, that the inhabitants of the iſland, on ſeeing a branch of the common coffee-tree with leaves and fruit, brought from Mocha in a French ſhip, inſtantly recollected that they had obſerved a ſimilar tree growing wild on their mountains, which was ſoon after produced, and found to be little different. 3. C. *guianenſis*. Mart. 5. Lam. 3. Willd. 6. Aubl. Guian. 1. tab. 57. "Leaves lanceolate; peduncles axillary, aggregate; corollas quadrifid." Willd. "Flowers quadrifid; berries ſmall, violet-coloured, with two ſeeds." Aubl. A ſhrub, one or two feet high. *Branches* quadrangular, knotty. *Leaves* oppoſite, brachiate, acute, quite entire, green, ſmooth, ſhining, on ſhort petioles. *Stipules* two at each joint, oppoſite, intrafoliaceous, acute. *Flowers* white, ſeſſile. *Berries* ſpherical. *Seeds* coriaceous. A native of Guiana. 4. C. *triflora*. Mart. 10. Willd. 5. Forſt. Prod. 95. "Leaves ovate-lanceolate, acuminate; peduncles three, terminal, one-flowered." A native of Otaheite. 5. C. *paniculata*. Mart. 6. Lam. 4. Willd. 7. Aubl. Guian. 1. tab. 58. "Leaves oblong, acuminate; panicle terminal, divaricated; corollas quadrifid; branches quadrangular." Willd. "Branches quadrangular; leaves large, ovate-oblong, acute; corollas quadrifid; berries with two ſeeds." Aubl. A ſhrub. *Trunk* ſeven or eight feet high, five or ſix inches in diameter; covered with a grey, wrinkled, cracked bark. *Branches* oppoſite, compound, knotty. *Leaves* oppoſite, brachiate, on on short petioles. *Stipules* intrafoliaceous, caducous. *Flowers* white, sweet-scented; peduncles quadrangular, with opposite brachiate ramifications; calyx four-toothed; stamens four. *Berries* bluish; one of the seeds frequently abortive. A native of Guiana. 6. C. *occidentalis*. Linn. Sp. Pl. 2. Mart. 2. Lam. 5. Willd. 8. Jacq. Amer. 67. tab. 47. (Pavetta, Brown. Jam. 142. tab. 6. fig. 1. Jasminum, Burm. Amer. tab. 156. fig. 2.) "Flowers four-cleft; berries with one seed." Linn. "Leaves oblong-lanceolate, acuminate; panicle terminal, trifid, few-flowered; berries with one seed; little branches quadrangular." Willd. A shrub about six feet high. *Branches* long, compound, brittle. *Leaves* opposite, quite entire, shining, on short petioles. *Stipules* intrafoliaceous. *Flowers* white, sweet-scented; stamens four; anthers scarcely projecting beyond the tube. *Berries* roundish, about the size of an olive, crowned at the top, of a bluish black colour when ripe. *Seeds* solitary, roundish, cartilaginous, striated, enclosed in a membranous aril. A native of Jamaica, St. Domingo, and Martinico. 7. C. *racemosa*. Mart. 3. Lour. Cochin. 145. "Much branched; leaves rugged; racemes terminal; berries with two seeds." A small tree, only four feet high. *Branches* numerous, cylindrical, diffuse. *Leaves* opposite, ovate-lanceolate, quite entire, beset with many tubercles, on short petioles. *Flowers* in erect brachiate racemes; common peduncle long, quadrangular; partial ones shorter, cylindrical, opposite or stellate. *Berry* roundish, small, red, watery, one-celled, with two hemispherical seeds. A native of Mozambique. 8. C. *zanguebariæ*. Mart. 4. Lour. Cochin. 145. "Corollas six or seven-cleft; fruit angularly nerved, with two seeds." A small upright tree, six feet high. *Branches* thick, short, spreading. *Leaves* ovate-lanceolate, smooth, opposite. *Flowers* white, axillary, several together, on short one-flowered peduncles. *Berries* red, oblong-ovate, angular with longitudinal nerves. A native of Africa on the coast of Zanguebar; and cultivated near Mozambique with the preceding species. 9. C. *sambucina*. Mart. 7. Willd. 1. Forst. Prod. 92. "Leaves oblong-lanceolate, cymes corymbous, terminal." A native of the Friendly Islands. 10. C. *opulina*. Mart. 8 Willd. 2. Forst. Prod. 93. "Leaves ovate-lanceolate; cymes contracted, globular, terminal." A native of New Caledonia. 10. C. *odorata*. Mart. 9. Willd. 3. Forst. Prod. 94. "Leaves egg-shaped, acute; cymes corymbous, axillary." A native of Tanna and the Friendly Islands.

Propagation and Culture. None of the species, except the first, have been cultivated in Europe; and as this, like all the others, is a native of tropical climates, it is of course confined to our stoves, to which its evergreen-leaves, beautifully white flowers, and succeeding red berries, are a valuable ornament. It is raised most successfully from the berries, which must be fully ripe, and sown soon after they are gathered, for if kept out of the ground a short time, they will not grow. If fresh berries cannot be obtained, young plants must be procured in small pots. The pots in which the seeds are sown should be filled with a light kitchen-garden earth, plunged into a hot-bed of tanners' bark, and sparingly watered once or twice in a week. In a month or five weeks the plants will appear, and in two months more will be fit to transplant. As many of the berries will produce two plants, these must be carefully separated, and treated as before. The plants should have free air admitted to them every day according to the warmth of the season. In summer they will require frequent watering, but should have only a small quantity at a time. They should not be transplanted more than twice a year, and unless they have made great progress in their growth, once will be sufficient. The stove in which they are placed should be kept to the heat assigned for the ananas in the botanical thermometer.

COFFEE, in *Domestic Economy* and *Medicine*, the name of a well known potable liquor, made by a decoction, or simple infusion of the seeds of the coffee-berry, after they have been properly roasted, and ground to powder in a small mill, constructed for the purpose. Its introduction into the civilized world is comparatively of modern date. It was unknown to the Greeks and Romans; nor is it mentioned by any of the European writers who were engaged in the crusades; it could not, therefore, have been used in Syria during the 12th and 13th centuries. We are assured by Mr. Bruce, that it is a native of Abyssinia, and is found wild in great abundance from Caffa to the banks of the Nile.

It is also generally said to have been cultivated in that country from time immemorial. M. Lagrenée, one of the most intelligent agents that France ever had in the India service, says the abbé Raynal, procured some of the fruit, and made trial of it. He found it, as the abbé informs us, to be larger, rather longer, and almost as fragrant as that which is obtained from Arabia. That the qualities of the wild, or cultivated berry, have been long known in that part of Africa, is confirmed by Bruce. The Gallæ, he tells us, a wandering nation of Africa, in their incursions on Abyssinia, being obliged to traverse immense deserts, and being also desirous of falling upon the towns and villages in the cultivated part of Abyssinia without warning; carry nothing with them to eat, but coffee roasted till it can be pulverized, and then mixed with butter to a consistency, that will suffer it to be rolled up in balls, and put into a leathern bag. One of these, about the size of a billiard ball, keeps them, they say, in strength and spirits during a whole day's fatigue. better than a loaf of bread, or a meal of meat. Bruce's Travels, vol. ii. p. 226.

It is, however, from Arabia that coffee was first brought into Europe. Whether it is indigenous in that country, has not been positively ascertained; and it is not possible to reconcile the reports concerning it, which are given by different oriental writers. According to some, the use of it was first introduced by the prior of an Arabian monastery, who, being informed by a goat-herd of the effects produced on his goats, when they had happened to browse on the coffee-tree, gave an infusion of the berries to his monks, to prevent the inclination to sleep, which frequently interfered with the due performance of their nocturnal prayers. According to others, a mollack, named Chadely, was the first among the Arabians who made use of coffee, to relieve himself from a continual drowsiness which hindered him from attending punctually to his nightly devotions. His dervises did the same, and their example was followed by the lawyers. It was soon found out, that this liquor purified the blood by a gentle agitation; dissipated the crudities of the stomach, and raised the spirits; and, in consequence of these properties, it was soon adopted by those who had no occasion to keep themselves awake. Both these accounts, especially the former, clearly imply that the coffee-tree grew wild in Arabia at that time, but was not till then cultivated for the sake of its fruit. The author of an Arabian manuscript, formerly in the library of the king of France, and now deposited in the Bibliotheque Nationale, attributes the first introduction of this beverage into Arabia, to Megaleddin, mufti of Aden, about the middle of the 15th century. He is said to have met with it on a journey into Persia, where it was then only coming into use; and, on his return, to have employed it himself, and given it to the dervises, with whom he was accustomed to spend the night in prayer.

The

The example of the mufti rendered this new luxury popular in Aden, whence it rapidly extended to Mecca, Medina, and the other cities of Arabia Felix. Public coffee-houses were opened within a small space of time in Persia, as well as in those cities, which afforded a lounge to the idle, and a relaxation to the man of business. There the politician retailed the news, the poet recited his verses, and the mollacks delivered their sermons. The same of this bewitching potation quickly reached Grand Cairo, and was received with equal avidity at Constantinople. But in these populous cities, it did not obtain similar favour from the ruling powers. At Grand Cairo it was opposed on religious grounds. In the year 1511, it was prohibited by Khaiae Beg, from a persuasion that it had an inebriating quality, and produced inclinations forbidden by the Koran. But the prohibition was soon after taken off by his successor, Causon. In the year 1523, Abdallah Ibrahim again denounced it in a sermon delivered in the mosque of Hassananie. A violent commotion was produced, and the parties came to blows. Upon this the sheik, El-beiet, commander of the city, assembled the doctors, and, after giving a patient hearing to their tedious harangues, treated them all with coffee, first setting the example, by drinking it himself, and then dismissed the assembly without uttering another word. By this prudent conduct, the public peace was restored; and coffee continued to be drank at Grand Cairo without further molestation.

At Constantinople it had to encounter political, as well as religious, opposition. Religion, as usual, took the lead. The dervises had the sagacity to discover, that coffee, when roasted, has become a kind of coal; they, therefore, declaimed against it with fury, coal being one of the substances which their prophet declared not intended by God for human food. The mufti was of their party, and the coffee-houses were soon shut up. A more sensible mufti succeeded, who assured the faithful, that roasted coffee is not coal, and they were again opened. But, though religious superstition thus easily gave way to the seductive influence of sensitive enjoyment, a submission not at all uncommon, the political objections were not so readily silenced. The ever-trembling apprehensions of a despotic government found, or fancied that they found, in the public coffee-houses, receptacles for the disaffected, and nurseries of sedition. These dangerous places of resort were, consequently, always regarded with a jealous eye; and, after several vicissitudes of connivance and discouragement, were at length finally prohibited. But they were not deemed formidable beyond the precincts of Constantinople. They were of too much importance to the public revenue to be entirely suppressed, and were suffered to remain, without much restraint, in all other parts of the empire. Nor in the capital itself was the use of coffee in private families at all discouraged; scruples of conscience were no longer excited against it; and it has ever since been allowed to all ranks of men, with the full permission both of the mufti and of the civil government. The Turks have now a particular officer, whom they call *Kahveghi*, or inspector of coffee; and in the seraglio there are several Kahveghis, each of whom presides over twenty or thirty Battagis, who are solely employed in preparing this favourite liquor for the inhabitants. A refusal to supply a wife with coffee, is even said to be reckoned among the legal causes of a divorce.

The first mention of coffee in the west of Europe is by Rauwolff, a German traveller, who returned from Syria in 1573. The tree was particularly described in 1591 by Prosper Alpinus in his "Medicina Ægyptiorum," and also in his "History of Ægyptian Plants," printed at Venice in 1592. Its use, as a beverage, is noticed by two English travellers in the beginning of the 17th century; Biddulph about 1603, and William Finch in 1607. The former says, "The Turks have for their most common drink coffee; which is a black kind of drink, made of a kind of pulse, like pease, called *coava*." The latter, "The people in the island of Socotora have, for their best entertainment, a China dish of cobo, a black bitterish drink, made of a berry like a bay-berry brought from Mecca, supped off hot." Pietro della Valle, a Venetian, tells his friend in a letter written from Constantinople in 1615, that, upon his return, he should bring with him some coffee, which, he believed, was a thing unknown in his country. In France, it was introduced first at Marseilles, in the year 1644, by some gentlemen who accompanied Monf. de la Haye to Constantinople, and brought with them on their return, not only some coffee, but the proper apparatus and vessels for making and drinking it. In 1660, several bales were imported from Egypt: and in 1671, a coffee-house was opened at Marseilles, in the neighbourhood of the exchange, where people met to smoke, talk of business, and divert themselves with play. It was first brought to Paris in 1657, by the celebrated traveller Thevenot; but only in a small quantity, and consequently was confined to his own family and particular friends. By the public at large it was never seen, and scarcely heard of, but from the account of travellers. In 1669, it was more generally introduced by Soliman Aga, ambassador from the sultan Mahomet IV.: and in 1672, a public coffee-house was opened by an Armenian, called Pascal, who afterwards removed to London. But the use of coffee had been introduced in the English capital before the return of Thevenot from the East. For, in 1652, Daniel Edwards, a Turkish merchant, brought home with him a Greek servant, whose name was Pasqua, who understood the method of roasting and making it. This servant was the first that publicly sold coffee, and kept a house for that purpose in George Yard, Lombard-street. The first mention of coffee in our statute books is anno 1660 (12 Car. II. cap. 24.) when a duty of four-pence was laid upon every gallon of coffee made and sold, to be paid by the maker. In 1663, it was ordered, by a particular statute, that all coffee-houses should be licensed at the general quarter sessions of peace for the county. And in 1675, Charles II. issued a proclamation to shut them up as seminaries of sedition; but in a few days the proclamation was abrogated by a second. Since that time coffee is often mentioned in our statute books, but only with a view to the regulation of the duties. Ray, in his "History of Plants," published in 1688, supposes that there were then in London as many coffee-houses as in Grand Cairo itself, and that similar houses were to be met with in all the principal cities and towns in England. At the same time he expresses his surprize that the neighbouring countries should permit so rich a treasure to be confined to a single province, and wonders what watchful dragon is employed by the natives to prevent strangers from procuring either the plant itself or its recent seeds; which, he doubts not, would readily grow in a similar climate and soil to the great advantage of the cultivator. It cannot be imagined that the enterprising commercial nations of Western Europe, which have formed colonies in the tropical regions, would be inattentive to the value of such an acquisition. The Dutch were the first who made the attempt with success. We are informed by Boerhaave, in his "Index to the Leyden Garden," that Nicholas Witsen, burgomaster of Amsterdam, and governor of the East India company, instructed Van Hoorn, governor of Batavia, to procure from Mocha, in Arabia Felix, some berries of the coffee-tree to be sown at Batavia. This was accordingly done, and about 1690, many plants were raised

from

from ſeeds, one of which was ſent to the garden at Amſterdam, where it bore fruit, and in a ſhort time many other plants were raiſed from it. In the year 1714, the magiſtrates of Amſterdam ſent to Lewis XIV. a fine tree about five feet high, in full foliage, with both green and ripe fruit. This plant is ſaid by Du Tour to have been the parent of all that have ſince been cultivated in France and in the French Weſt India iſlands. In 1717, ſeveral plants were ſent to Martinico, under the care of M. de Clieux, who approved himſelf worthy of the truſt. For the voyage being long, and the weather unfavourable, they all died but one; and the whole ſhip's company being at length reduced to ſhort allowance of water, this zealous patriot divided his own ſhare between himſelf and the plant committed to his charge, and happily ſucceeded in bringing it ſafe to Martinico, where it flouriſhed, and afforded a ſtock for the neighbouring iſlands. In 1718, the Dutch colony at Surinam firſt began to plant coffee; and, in 1722, the French governor of Cayenne, having buſineſs at Surinam, contrived by an artifice to bring away a plant, which, in the year 1725, had produced many thouſands. In the year 1732, coffee was cultivated in Jamaica, and an act paſſed to encourage its growth in that iſland.

It is well known that the Arabian coffee is univerſally allowed to be better in quality, and conſequently bears a higher price than that which is raiſed in any of the European colonies. The reaſons that have been aſſigned for this difference may be reduced to five: 1. Difference of climate and ſoil. That part of Arabia where the coffee tree is cultivated is rocky, dry, and hot. At Batavia the ſoil is rich and deep; and in the rainy periods the quantity of wet that falls is exceſſive. Hence it is probable that the plant had in ſome meaſure degenerated before it arrived in Europe. Nor was it likely to be improved by its removal to the Weſt Indies, where it is generally cultivated on the richeſt ground. For though the planters know by experience that coffee grown in a light ſoil, and on dry and elevated ſlopes, ſuch as are choſen for it in Arabia, has a ſmaller berry, with a delicate flavour; while that which is produced in a low, fertile, and moiſt ſoil, has a larger berry, but comparatively flat and inſipid: yet, as they alſo learn from experience, that the trees in this rich ſoil commonly yield from twelve to ſixteen ounces per plant; while thoſe in the drier ſoils will ſcarcely furniſh more than from ſix to eight ounces, making a difference of one half in the weight; and as in all the European markets the ſtated difference in the price of each is only from 15 to 20 per cent. it is evidently their intereſt to raiſe their coffee in the richeſt ſoil, notwithſtanding the deterioration in the quality of the berry, which is the neceſſary conſequence. 2. The cuſtom of pollarding the trees, which is univerſal in almoſt all the French iſlands. The branches are obliged by this operation to take more of a lateral direction, in conſequence of which they grow thicker, and afford leſs acceſs to the rays of the ſun; they are alſo apt to become decumbent, and more expoſed to the moiſt evaporations of the ſoil: and hence, as Du Tour imagines, the berries are ſeldom perfectly ripened. 3. Gathering the fruit before it is perfectly ripe, and not drying it in a proper manner. In Arabia the coffee berries are not gathered till they readily fall off on ſhaking the tree, when they are received on linen ſheets ſpread for the purpoſe, and are then removed to a ſituation where they can be completely dried in the ſhade on mats, which are fitted to imbibe their moiſture. But in the Weſt Indies this cannot be effected, for though the air in thoſe climates is hot, it is always ſo damp, that coffee could never be dried in the ſhade, ſufficiently for exportation to Europe. The rains, moreover, which are then very frequent, often make the berries fall before they are perfectly ripe. Du Tour recommends the drying of them in ſtoves. The method of curing coffee in the Weſt Indies, as it is deſcribed by Dr. Titford of Spaniſh-town, Jamaica, (ſee the 9th volume of the Tranſactions of the Society of Arts, &c.) is as follows: They bring the coffee-berries, after they are ripened on the trees, to a machine called a peeling-mill, where it is diveſted of its outer ſkin and pulp: after which it is put in heaps, and undergoes a ſlight fermentation, which is then ſpread out and dried on platforms or terraces, until it is perfectly cured, when it is ſtored till the whole crop is got in. When this work is completed, they begin to prepare it for market, by again putting it in the ſun, and carrying it to the peeling and winnowing-mills, where it is totally diveſted of its coats and impurities, and the broken and bad coffee picked out, &c.; after which it is fit for market. The ſmall and needy planters, however, who have no mills, beat out their coffee in large wooden mortars, or troughs, which occaſion a waſte by breaking the berry. When any coffee is kept for private uſe, or iſland conſumption, it does not undergo the above proceſſes; but the ripe fruit, as it is picked from the tree, is ſpread out in the ſun, and ſimply well dried, and beat out as it is wanted for uſe or ſale. Coffee is well known to improve, when ſo preſerved, by drying it in the berry; but to be impaired, when it is diveſted of its coverings, as it is now ſent to market. Dr. Titford, therefore, recommends its being ſent home, in the whole berry, well dried. One advantage attending this mode is the ſaving of the labour to the negro, and conſequent expence to the planter; and another is the prevention of the coffee's imbibing the ill flavour of ſugar, rum, pimento, &c. which may be ſhipped with it, and which, it is ſaid, is the principal objection to the uſe of the Weſt India coffee in England. 4. Want of proper care in ſtowing them for the voyage. If they come in a ſhip with raw ſugars and rum, they are ſure to contract a taſte which cannot be driven off by the ſubſequent roaſting. The French are in this reſpect much more attentive than the Engliſh, and, in conſequence, their coffee, eſpecially that from the Windward iſlands, is commonly better. This ſuperiority is the effect of peculiar circumſtances. Moſt of the Engliſh ſhips are hired for the freight; the captains ſtow the goods as they receive them, and the owners are ſatisfied, if the veſſel is but well filled. The French ſhips are generally laden for the proprietor's own uſe; the captains buy the goods themſelves; and that they may be able to give a good account of their management, they are obliged to pay great attention to the ſtowage of their veſſel, and the preſervation of their cargoes. 5. Uſing the coffee-berries too ſoon. Dr. Browne aſſerts, that the worſt coffee produced in America will, in a courſe of years, not exceeding fourteen or fifteen, be as good, parch and mix as well, and have as high a flavour, as the beſt we now have from Turkey, if kept in a dry place, and properly preſerved; and that ſmall-grained coffee, or that which is raiſed in a dry ſoil and warm ſituation, will, in about three years, be as good as that which is now uſed in the London coffee-houſes. Du Tour, on the other hand, aſſerts, that whether it be old or new is of little importance, provided it have been gathered when fully ripe, and have loſt all its vegetable juices. He is, moreover, of opinion that, *cæteris paribus*, it is always beſt when new; and aſſures us that he has drank in St. Domingo the coffee of that country made of berries gathered only ſix weeks before, which was not worſe, if not better, than Mocha coffee that was three years old. It is true, he adds, that he gathered the berries himſelf when they were juſt ready to fall, deprived

prived them immediately of their pulp, dried the feeds in the fun as fpeedily as poffible, and roafted them when they ceafed to diminifh in fize, and when he could fcarcely break them with his teeth. In all other refpects he treated the two kinds of coffee in the fame manner, and made ufe of them in equal proportions.

Thus, in the courfe of three centuries and a half, has a berry, which was not before known as an article of food, except to fome favage tribes in the confines of Abyffinia, made its way through the whole civilized world. In the nations which profefs the religion of Mahomet, it is drunk at leaft twice a day by all ranks of men, from the fultan and mufti to the artificer and the peafant. Among the profeffors of Chriftianity, by whom it has been known little more than a century and a half, it is ftill regarded rather as a luxury, and is ufed only by the middle and upper claffes. In England, indeed, tea is moft generally preferred; but on the continent, efpecially in France, coffee is in univerfal requeft. In confequence of this prevailing fafhion, the tree which produces it is now extenfively cultivated in the tropical climates of both hemifpheres. Of Arabia Felix it may be reckoned the moft valuable produce. The Dutch, as we have feen, early introduced it into the ifland of Java, and foon after into Ceylon. The Englifh have plantations of it about Madras; the French once had at Pondicherry, and ftill raife it in great quantities in the Ifles of France and of Bourbon. In America it is cultivated by the colonifts of thefe three maritime powers, and in fome degree by the Spaniards. It is not poffible to procure an accurate account of the quantity that is raifed and confumed; but fome idea may be formed from the following partial details.

	Pounds Weight.	
Arabia furnifhes annually to the European companies	1,500,000	
——— Perfians	3,500.000	
——— fleet from Suez	6,500,000	
——— to Hindooftan, the Maldives, and the Arabian colonies on the coaft of Africa	50,000	
——— to the Caravans	1,000,000	
Total	12,550,000	Raynal.

Surinam exported in 1775		15,387,000	Do.
Martinico		9,688,960	Do.
Guadaloupe		6,302,902	Do.
Cayenne		65,888	Do.
St. Domingo exported in 1767		12,197,977	Do.
———	in 1775	45,933,941	Do.
———	immediately before the French revolution	71,663,187	Edwards.
St. Lucia	in 1752	about 5,000,000	Raynal.
Porto Rico	in 1778	1,116,325	Do.
Grenada	in 1776	1,827,166	Edwards.
———	in 1787	987,004	Do.
St. Vincent	in 1787	71,041	Do.
Dominica	in 1787	2,032,778	Do.
———	in favourable years	3,000,000	Do.
Jamaica	in 1768	420,300	Do.
———	in 1774	650,700	Do.
———	in 1787	716,315	Do.
———	in 1790	1,783,740	Do.

A pound of coffee is generally more than the produce of a fingle tree; but vigorous trees of a proper age fometimes produce four pounds or more; and at Surinam fome that were five years old and eighteen feet high, have been known to produce even feven pounds.

The Arabians and Turks drink their coffee very hot, and without fugar. People of the firft fafhion ufe only what is called fultana coffee, made of the dried pulp of the berry. This pulp, after it has been bruifed, is put into an iron or earthen pan, placed on a charcoal fire, and ftirred about till it becomes a little brown, but not of fo deep a colour as the common coffee; it is then thrown into boiling water, with the addition of at leaft a fourth part of the membranous hufk or aril of the feeds, commonly called, in the Weft Indies, the parchment. The whole is boiled together in the manner of common coffee. The feeds are thought by the Arabians to be too heating; the common people, therefore, generally ufe a weak liquor made of the membranous hufks alone. Thefe, as well as the pulpy part, are carefully taken off from all the coffee that is fent to the weft of Europe, and the feeds, becoming dry, foon lofe their vegetative life. The excellence of our coffee depends in a great meafure on the fkill and attention employed in the roafting; if done too little, it has little flavour, and lies heavy on the ftomach; if too much, it becomes acrid, acquires a difagreeable burnt tafte, and is rendered pernicious, or at leaft, is deprived of its beft qualities; whereas, according to Du Tour, the action of fire, when nicely regulated, takes away its rawnefs, and the aqueous part of its mucilage, deprives it of its faline qualities, and gives it that empyreumatic fcent, which is fo pleafant and refrefhing, and which is fomewhat fimilar, but greatly fuperior, to that produced by broiling meat on a gridiron.

In England the feeds are commonly roafted in a cylindrical tin box, perforated with numerous holes, and fixed upon a fpit which runs longitudinally through the centre, and is turned by means of a jack. The whole is fufpended over a large charcoal fire in a femicircular hearth; or, as in Yorkfhire, placed directly in front of the large kitchen fire, and taken off occafionally, that the berries may be fhaken and preferved from burning. When the oil rifes, and the feeds have a dark brown colour, it is emptied into receivers made

made with large hoops, and with iron plates at the bottom; there the coffee is again ſhaken and left to cool. If it look bright and oily, it is a ſign that it is well done. In Perſia boiling water is frequently poured upon the entire ſeeds, which makes a weak, but agreeable infuſion. And in Europe ſome are of opinion that the coffee has a more delicate flavour when the ſeeds have only been bruiſed or pounded in a mortar; but the common method is to grind it in a mill to a fine powder. It is generally allowed that it is much the beſt when it has been recently roaſted. The powdered coffee is ſometimes put into a linen bag or ſtrainer, ſuſpended at the mouth of a coffee-can, or as it is called in the north of England, a coffee-biggin: boiling water is then poured upon it, till the can is ſo full as to keep the ſtrainer completely immerſed in the hot water. When it has ſtood a ſufficient time, the liquor is conveyed through the ſpout of the can, clear of the coffee grounds. This is pronounced by Du Tour to be a good method. But, in his opinion, the following is much better. Let the powder be poured into a coffee-pot filled with boiling water in the proportion of two ounces and a half to two pounds, or two Engliſh pints of water: let the mixture be ſtirred with a ſpoon, and the coffee-pot be ſoon taken off the fire, but ſuffered to remain cloſely ſhut, for at leaſt two hours on the warm aſhes. During the infuſion, the liquor ſhould be ſeveral times agitated by a chocolate frother, or ſomething of the ſame kind, and be finally left for about a quarter of an hour to ſettle. Coffee thus prepared, adds the experienced French naturaliſt, is perfect. In France coffee is almoſt univerſally made ſtronger than in England. The Engliſh, ſays a lively French traveller, care little about the quality of their coffee, if they can but get enough of it. Dr. Fothergil recommends the following method of making it for breakfaſt: Let it be made in the uſual manner, only a third part ſtronger than uſual, and let as much boiling milk be added to it before it is taken from the fire, as there is water. When it has ſettled, drink it either with cream or without, but with very little ſugar, which is apt to make it become acid on weak ſtomachs. Our Engliſh phyſician was of opinion, that if our poor and middling people were able to procure this, it would be much more nouriſhing and beneficial than the wretched beverage of ordinary tea, in which they now indulge themſelves.

In none of the ſtates of Chriſtendom was the uſe of coffee oppoſed by religious fanaticiſm; nor had it to encounter political jealouſy, except for a few days in the reign of our Charles II. But, like every other ſubject which has occupied the human mind, it could not fail to occaſion a difference of opinion. Among the profeſſors of medicine in particular, it met with aſſailants and abettors. The Theſis, entitled *Potus Coffeæ*, delivered by a Swediſh ſtudent in the univerſity of Upſal, and publiſhed in the "Amænitates Academicæ" under the direction of Linnæus himſelf, is a ſarcaſtic entertaining invective againſt the introduction of this novel luxury, which the patriotic youth apprehended would vitiate the native taſte, and debauch the ſimple manners of his countrymen. He accordingly inveighs againſt it with an honeſt indignation, as one of the pernicious irrational indulgences which had been imported into Sweden from degenerate France; and gives a ludicrous liſt of the expenſive utenſils required for its uſe in that faſhionable ſtyle which the vanity of his fair country women would not permit them to forego; and enumerates, with ſomewhat of a triumphant ſatisfaction, the numerous bodily diſorders, which it has been known, or is likely to generate. Nor is it without ſome reluctance that he acknowledges its beneficial effects in a few particular caſes. Others, on the contrary, are as vehement in its praiſe. If we may believe Du Tour, it baniſhes languor and anxiety, gives thoſe who drink it a pleaſing ſenſation of their own well-being, and diffuſes through their whole frame a vivifying delightful warmth; it is alſo highly favourable to the ſocial virtues, promotes cheerful converſation, ſharpens the capacity for witty repartee, ſmooths the wrinkled brow, and is ſometimes able to convert enemies into friends. Did it certainly poſſeſs the latter property, who would not devoutly wiſh that Napoleon and all the other monarchs of Europe, without inquiring whether they have acquired their crowns by uſurpation or by legal hereditary ſucceſſion, would meet once a year, each accompanied by his prime miniſter, and take an exhilarating cup of coffee together? How in that caſe would they ſmile upon each other, and in what good humour would they return to their reſpective palaces, to diſcharge, with benevolent faithfulneſs, the important duties of their elevated ſtation! But to deſcend from theſe extravagancies of cenſure and panegyric, the truth ſeems to be, that coffee, like tea, has different effects upon different conſtitutions, and that phyſicians are inclined to recommend or diſparage the one or the other, as it happens to agree or to diſagree with their own. Dr. Fothergil did not venture to decide which of the two is abſolutely the beſt. From his perſonal experience he preferred coffee; but obſerves that neither of them afford any material ſupport, and that they are rather the vehicles of nouriſhment than nutritious of themſelves. The complaints ſaid to have been produced by the frequent or exceſſive uſe of coffee are habitual head-achs, vertigo, tremors, maſculine imbecility, pimples of the face, weakened viſion, and according to profeſſor Murray, apoplexy. It has alſo been ſuſpected of producing palſies, and Dr. Percival aſſures us, from his own obſervation, that the ſuſpicion is not altogether without foundation. As it produces or aggravates hyſterical and hypochondriacal affections, Tiſſot cautions literary and ſedentary people againſt its uſe. To thoſe, however, who are inclined to trim the midnight lamp, it cannot but be acceptable: but they will perhaps do well to uſe it rather as an occaſional refreſhment than a regular beverage. Coffee, ſays Dr. Percival, is ſlightly aſtringent and antiſeptic; it moderates alimentary fermentation, and is powerfully ſedative. Its action on the nervous ſyſtem probably depends upon the oil which it contains, which receives its flavour, and is rendered mildly empyreumatic by the proceſs of roaſting. Its medicinal qualities ſeem to be derived from the grateful ſenſation it produces on the ſtomach, and from the ſedative powers it exerts on the *vis vitæ*. Hence it aſſiſts digeſtion, and relieves the head-ach; but in delicate habits, it often occaſions watchfulneſs, tremors, and many of thoſe complaints which are denominated nervous. Dr. Fothergil thought the French practice of drinking coffee immediately after dinner, with a view to promote digeſtion, much better than our cuſtom of taking it later in the evening; and that at any rate it is a deſirable ſubſtitute for the bottle, which, in England and the northern parts of Europe, detains the gentlemen at the dinner-table ſo long after the cloth is drawn, to the prejudice of their health, and ſometimes to the injury of their fortunes. (See Ellis's Hiſtory of Coffee. The abbé Raynal's Hiſtory of European Settlements: French Edition of 1780. Bruce's Travels in Abyſſinia. Edwards's Hiſtory of the Britiſh Weſt India Iſlands. Woodville's Medical Botany. Du Tour in Nouveaux Dictionaire d'Hiſtorie Naturelle, and Dictionaire Encyclopedie Methodique, Agriculture, under the word Caffayer).

By

By 43 G. III. c. 68. all former duties of customs on coffee are repealed, and the following new duties imposed: For that which is the produce of any British colony or plantation in America, or of any other country or place, on importation, to be secured in warehouses, 6*d.* per cwt.; and when taken out of such warehouses for home consumption, 5*d.* per lb. By 43 G. III. c. 69. all former duties of excise are in like manner repealed, and in lieu of them the following are imposed: For every lb. weight avoirdupoise of coffee, of the growth or produce of any British colony or plantation in America, imported into Great Britain, 1*s.* 1*d.*; for the same, if imported by the East India Company, 1*s.* 6*d.*; and for the same of all other coffee imported into Great Britain, 2*s.* No coffee shall be imported into Great Britain otherwise than in chests, cases, or packages, containing at least 112 lb., on pain of forfeiting the same; and none other shall be entered for exportation. 5 G. III. c. 43. 23 G. III. c. 79. 42 G. III. c. 93. Officers of the excise and customs may go on board ships, search, and seize. 11 G. III. c. 80. By 5 G. III. c. 43. if any vessel, coming from foreign parts, having on board 20 lbs. of coffee, shall be found at anchor, or hovering within two leagues of the shore, the coffee shall be forfeited, and the vessel, &c. be also forfeited, provided such vessel doth not exceed the burden of 50 tons. By 35 G. III. c. 118. the commissioners of excise shall provide near to the respective ports warehouses for lodging coffee and cocoa-nuts: and officers of excise shall mark every cask or package of these articles on board of ships importing them: and if they are shipped before they are marked, they shall be forfeited and seized. When they are taken out of warehouses, the proprietor shall give written notice to the officers, if for home consumption one hour, if for exportation 12 hours; bring them to be weighed, and pay the duty. On producing a certificate of the payment of the duties, a permit for the removal of them shall be granted. The importer, within 30 days after the entry of the vessel, shall enter the coffee, cocoa-nuts, &c. with the officer of excise appointed for this purpose; and the same shall be landed or warehoused, on paying or securing the duties. In default of such entry, the same shall be deemed clandestinely run, and forfeited. 10 G. c. 10. 5 G. III. c. 43. Coffee, &c. not removed, and delivered within the time, specified in the permit, shall be deemed as removed without permit. Coffee, and also tea, intended to be taken out for exportation, shall be delivered on security given that they shall be exported, and not relanded; which security shall be discharged, on a certificate under the common seal of the chief magistrate beyond the seas, or under the hands and seals of two known British merchants there, that the same were landed, or on proof by credible persons, that they were taken by enemies, or perished in the seas. 10 G. c. 10. By 21 G. III. c. 55. no damaged coffee, which cannot be sold for 1*s.* 6*d.* a pound, nor cocoa-nuts for 1*s.* a pound, shall be sold to be consumed in this kingdom, but secured in warehouses, and not taken out till security be given for the exportation of them. Officers of excise seizing forfeited coffee, &c. shall be allowed one-third of the clear sum that shall arise from the sale after condemnation, &c. 21 G. III. c. 55. Every person keeping a public-house, shop, &c. for selling of brandy and other spirituous liquors, who shall have in his custody coffee, tea, chocolate, or cocoa-nuts above 6 lbs. weight, shall be deemed a dealer in such articles. 11 G. c. 30. By 20 G. III. c. 35. no person shall sell any coffee, &c. without a licence; for which he shall pay (by 43 G. III. c. 69.) 5*s.* 6*d.* to be annually renewed: and selling without such licence, incurs a forfeiture of 20*l.* Houses of manufacturing and sale are to be entered at the office for the division on pain of forfeiting 200*l.* and the goods, &c. 10 G. c. 10. Every house, in which coffee, tea, cocoa-nuts, or chocolate shall be sold, must have an inscription over the door, "dealer in coffee, tea, &c." on pain of 200*l.* And persons buying any of the said articles of a person not having such inscription over his door, shall forfeit 100*l.* Persons having such inscription without entry of their houses, shall forfeit 50*l.* over and above the penalties for selling or dealing without entry. 19 G. III. c. 69. Officers may enter houses, &c. where such articles are sold, to survey and weigh, and in weighing, be assisted by the owner, who shall keep just weights and scales, on pain of 100*l.* and forfeiture of the same. 10 G. c. 10. 10 G. III. c. 44. 28 G. III. c. 37. Deceiving or obstructing the officer incurs a forfeiture of 100*l.* 26 G. III. c. 77. If any person shall obstruct an officer searching for goods supposed to be concealed, he shall forfeit 100*l.*; and the seller or dealer concealing the said articles, shall forfeit the same, and treble value, with package, &c.; and the obstruction of an officer in seizing or removing the said goods incurs a forfeiture of 50*l.* 10 G. c. 10. No person shall mix with coffee, any butter or other materials, to increase the weight, and knowingly buy or sell any so mixed, under forfeiture of 100*l.* 11 G. c. 30. Roasting houses shall be appointed by the commissioners, with proper officers and persons skilled in roasting, and persons having paid the duties may have their coffee berries roasted for 8*s.* per. cwt.; or the sellers and dealers may find their own roasters, paying 3*s.* per cwt. By 48 G. III. c. 129. if any article, made to resemble coffee or cocoa, be found in the possession of any dealer, or called by him English or British coffee, &c. it shall be forfeited, and the dealer shall forfeit 100*l.* All sellers and dealers of coffee, &c. shall keep a daily account of all coffee, tea, chocolate, and cocoa-nuts sold in small quantities under 6 lbs.; and also an account of each parcel above 6 lbs. sold in each day, in books prepared by the commissioners, to be returned to the officer upon oath of the truth of the entries: and neglect of doing the same shall incur a forfeiture of 100*l.* 10 G. c. 10. The commissioners shall cause all coffee and tea seized in London and condemned, to be sold there; and if seized elsewhere, they shall cause it, after condemnation, to be brought and sold in London; or, after having been valued by sworn valuers, they may be sold where the commissioners shall think proper. 12 G. c. 28.

COFFEE-*Berries*, in *Natural History*. These are figured pyritæ found in the cliff of Shepey island, and thought to resemble the berries of the coffee-tree in their external form, by Mr. Jacob, who published an account thereof at the end of his "Plantæ Favershamenses."

COFFER, a long square box about three feet long, and one and a half broad, used for breaking in pieces tin ore in a stamping-mill.

COFFER, *Capsa*, in *Architecture*, a square depressure, or sinking, in each interval between the modillions of the Corinthian cornice; originally filled up with a rose, sometimes with a pomgranate, or other enrichment.

These sinkings, called also *panels*, are of different figures in the compartments of vaults and soffits.

COFFER, in French *Coffre*, in *Fortification*, a hollow lodgment, or little ditch made in the great ditch when it is dry, and has no fausse-bray. Coffers are made opposite to or before the flanks of the bastions, are from 15 to 20 feet wide, from six to seven feet deep, and are covered with planks and earth raised about two feet higher than the level of the bottom of the ditch, after the manner of a parapet, in order to have embrasures in them for small pieces of artillery to defend the faces of the opposite bastions, and to prevent the passing of the ditch. Inftead of coffers, caponiers are frequently made acrofs the ditch, oppofite to the middles of the tenailles or curtains, which are lodgments four or five feet deep, having on each fide a palifaded parapet about three feet high, as a double covered way, to cover the mufqueteers lodged in it, who fire through the meurtrieres, and pafs through fuch caponiers to get to the outworks. Thefe are alfo made often upon the *glacis* of the *efplanade*, to repel the enemy when he endeavours to take the covered way. Coffers are of ufe only to the befieged. The chamber of a mine is alfo called *coffre*.

Coffer, *Coffre a feu*, confifts of feveral coffers filled with fire-works, and other combuftible materials, which they conceal in places, by which they fuppofe or fufpect the enemy will fend fome foldiers to attempt an enterprife. They fet fire to it by means of a train of powder, or by a faucisfon.

Coffer *of a horfe*, denotes the hollow formed by the contour of the ribs. See Horse.

Coffer, or *Cradle*, in *Inland Navigation*, denotes a large wooden trunk or veffel open at top, with moveable ends, large enough to receive a barge or veffel from a canal, in order to its being hoifted into a higher pound of a canal, or let down from it. See fubftitutes for locks in our article Canal. See Canal and Lock.

COFFER-DAM, a term in *Enginery* for a circular double range of piles, with clay rammed between, formed round any entrance lock to a dock, bafon, or canal, where the fame cannot otherwife be laid dry for digging out and building the foundations. See our articles Canal and Lock.

Coffer-Dam, *Batardeau*, Fr.; an enclofure ufed in laying the foundations of bridges and other aquatic buildings. The earlieft mention of coffer-dams occurs in the writings of Alberti, cap. 6. lib. 2. "Make," fays he, "the foundations of your piers in autumn when the water is loweft, having firft raifed an enclofure to keep off the water, which may be done in this manner. Drive in a double row of ftakes, very clofe and thick fet, with their heads above the top of the water like a trench; then put hurdles within this double row of ftakes, clofe to that fide of the row which is next to the intended pier, and fill up the hollow between the two rows with rufhes and mud, ramming them together fo hard that no water can get through; then whatever you find within the enclofure, water, mud, fand, or whatever elfe is a hindrance to you, throw them out, and dig till you come to a folid foundation." This method recommended by Alberti, will anfwer for fhallow water, but the coffer-dams in deep and rapid rivers muft be conftructed with four or fix rows of ftrong piles connected together with ties, to form a framework of timber, and covered on each fide with a fheeting of planks; then the interftices of the frame are to be filled in with clay or chalk carefully rammed to make the whole ftaunch.

COFFERER *of the King's Houfehold*, a principal officer in the court, next under the comptroller; who, in the compting-houfe, and elfewhere at other times, has a fpecial charge and overfight of other officers of the houfe, for their good demeanour and carriage in their offices; to all whom he pays the wages. See Household.

COFFIN, in a general fenfe, a wooden box or trunk, into which the bodies of dead perfons are put, in order for burial.

Coffins, at various periods, have been made of very different materials. Coffins formed of a fingle ftone, hollowed with a chiffel, are attributed by Mr. Gough to the Romans. They were fometimes of marble. Some of them contained two or more bodies, others only one; in which cafe it was not unufual for them to be made to fit the body, with cavities for the reception of the head, arms, and other protuberances. The folid ftone, or marble coffin, often curioufly wrought, was in ufe among the firft Chriftians in England; who, in all probability, copied the cuftoms of the Romans, after the conquerors had quitted our ifland. The coffin, called "kiftvaen," found among ancient relics in this kingdom, was compofed of rough ftones, fet edgeways at the fides and ends, and covered with one or more flat ftones. Sometimes the ftones were cemented together fo that the joints were not difcernible, and fometimes they were compofed of baked clay or tiles. The leaden coffin was in ufe among the Romans, not only for the reception of the body, but, in many inftances, for the afhes and bones. It was adopted by the Chriftians, and continues in frequent ufe to the prefent time, efpecially among the more opulent. However, lead was not the only metal ufed for coffins. Alexander was buried in a golden coffin by his fucceffor Ptolemy; and Mr. Gough fays, that glafs coffins have been found in England. The moft ancient inftance of wooden coffins on record among us, is that of king Arthur, who was buried in an entire trunk of oak, hollowed. The monk of Glaftonbury calls it "Sarcophagus ligneus." On this fubject fee Gough's Sepulchral Monuments in Great Britain, part i. fol. 1786.

The great improvements which took place in the cafting of iron about 20 or 30 years ago, enabling large articles to be run much thinner than before, fuggefted the introduction of caft-iron coffins; thefe were caft at fome of the Yorkfhire founderies, of different fizes, extremely thin, and fo apportioned, that they packed one within another, after the manner of nefts of pill-boxes, for the convenience of carriage. From not having heard of thefe iron coffins of late, we apprehend that they were not found to anfwer in point of expence. The increafing practice of ftealing dead bodies out of church-yards and burying grounds, for the ufe of the anatomical fchools, and lecture rooms of the metropolis, having excited the alarms of a great number of perfons, on the 5th of July, 1796, Mr. Gabriel Aughtie took out a patent for an improved kind of coffin, which fhould render the ftealing of bodies therefrom very difficult, if not impoffible. Thefe patent coffins are made of wood, in the common way, except that no faw-curfs are made in the fides for facilitating their bending to the fhape, and by which the fides of common coffins are fo much weakened; the infide of the bottom, fides, end, and top, are fecured by iron plating, and with angle pieces, from being cut or forced open; on the under-fide of the lid are fixed eight double fpring-catches, and within the top of the fides, eight brafs fockets, exactly fitted to the catches, fo that when the coffin is to be finally clofed thefe fpring-catches enter the fockets, and by fpringing open when the lid is clofe put down, they effectually fecure the lid from being again removed, as no tool or inftrument can be introduced to contract the fprings again, and prepare them for being drawn back. Between thefe fpring-catches the patentee employs fcrews to further fecure the lid, fimilar to thofe ufed in common, except that each fcrew head has both halves of it filed away in a bevelled form, and in contrary directions, fo that the fcrew-driver has perfect hold for driving or fcrewing them in, but none for drawing or unfcrewing them again. For further fecurity, thefe patent fcrews have their heads let into the lid, and a plug of wood, which matches the grain of the wood in the lid, is fitted in upon them, fo as to conceal the places of thefe fcrews.

Coffin, in the *Manege*, the whole hoof of a horfe's foot, above the coronet; including the coffin-bone, the sole, and the frush.

COFFIN *bone*, is a small spongy bone, enclosed in the midst of the hoof, and possessing the whole form of the foot.

COFFIN-*joint*, is that where the lesser pastern joins the foot. A strain in this joint occasions a stiffness, which can only be removed by blistering and firing.

COFFIN, *in the Manufacture of China*. See CASSETTE.

COG, in *Mechanics*. See MILL and WHEEL.

COGA, in *Geography*, an island of Abyssinia, in the lake of Dembea.

COGÆONUM, in *Ancient Geography*, the name of a river and of a mountain, placed by Strabo in the country of the Getæ. He says, that Zamolxis customarily resided on this mountain, and that the Getæ, after having deified him, gave it the epithet of "Sacred."

COGAMUS, a river of Asia Minor, at the foot of mount Imolus, according to Pliny, l. v. c. 29.

COGARETO, in *Geography*, a town of Italy, in the state of Genoa; 9 miles E.N.E. of Savona.

COGEAD, a lake of North America, 50 miles long, and 10 broad. N. lat. 66°. W. long. 109°.

COGEDUS, or CONGEDUS, in *Ancient Geography*, a river of Spain, in Celtiberia, and in the vicinity of Bilbilis. It is thought to be the present "Rio de Codes," which runs into the Xalon.

COGGESHALL, in *Geography*, a town of England, in the county of Essex, with a weekly market on Thursdays; 9½ miles W. of Colchester, and 44 N.E. of London.

COGGESHALL'S *Sliding-rule*, an instrument used in gauging, so called from its inventor. See the description and use under SLIDING-RULE.

COGGIA, or COCIA, in *Geography*, a town of the island of Corsica; 6 miles S. of Vico.

COGGLE, or COG, a small fishing-boat upon the coasts of Yorkshire; and *cogs (cogones)* are a kind of little ships or vessels used in the rivers Ouse and Humber. Stat. 23 H. VIII. c. 18. *Præparatis* cogonibus, *galles, & aliis navibus, &c.* Mat. Paris, an. 1066. And hence the cogmen, boatmen, and seamen, who, after shipwreck or losses by sea, travelled and wandered about to defraud the people by begging and stealing; until they were restrained by divers good laws.

COGHAN, WILLIAM, in *Biography*, master of arts, and bachelor of physic (as he calls himself in the title to his work), was born in Somersetshire, about the middle of the 16th century. He received his academical education at the university of Oxford; was made bachelor of arts, and fellow of Oriel college in 1563, and bachelor in medicine in 1574. The year following he quitted Oxford, having been appointed master of the school at Manchester, where he also practised in his profession, to the time of his death, which happened in the year 1607. In the year 1584, he published "The Haven of Health," chiefly gathered for the comfort of students, amplified upon five words of Hippocrates, *viz.* "labor, cibus, potio, somnus, venus;" whereunto is added, "A Preservation from the Pestilence, with a short Censure of the late Sicknefs at Oxford." It is a very curious book, full of quotations from the classics, recommending temperance and exercise, as the best preservatives and restorers of health. Towards the end of the volume, he has given a brief historical account of the sweating sicknefs, and of the sicknefs which happened at Oxford in 1575. "It began," he says, "on the sixth day of July, from which day to the twelfth day of August next ensuing, there died five hundred and ten persons, all men and no women." As the author was there at the time, we are obliged to give credit to this strange circumstance, of which no parallel, as far as we know, is to be found. Coghan also published in 1602, "An Epitome of the familiar Epistles, and some of the Orations of Cicero," for the use, we presume, of his school. Wood's Athenæ Oxon.

COGHNAWAGA, in *Geography*. See CAGHNEWAJA.

COGITATION, the act or operation of thinking. See THINKING.

COGLIANO, in *Geography*, a town of Naples, in the province of Principato Citra; 13 miles N.N.W. of Can[illegible].

COGNABANDA, in *Ancient Geography*, a town of India, on this side of the Ganges, according to Ptolemy.

COGNABARA, or COGNANDAVA, a town of India, on this side the Ganges. Ptolemy.

COGNAC, in *Geography*, a town of France, and principal place of a district in the department of the Charente, seated on the river Charente, and having a sub-prefect and a court of justice. The town contains 2827, and the canton 11,358 inhabitants. The territory comprehends 235 kiliometres and 19 communes. The whole district includes 70 communes, 785 kiliometres, and a population amounting to 44,145 persons. It has four cantons, *viz.* Cognac, Chateauneuf, Jarnae-Charente, and Segonzac. The soil is very fertile, and produces in abundance corn, wine, and fruit. It has always been famous for its brandy; and carries on a considerable trade not only in brandy, but in wine, both red and white, spirit of wine, and linseed. It has also some manufactures of earthen ware. Cognac is 7 leagues W. of Angoulesme. N. lat. 45° 42′. W. long. 20° 28′.

COGNAC, a town of France, in the department of the Upper Vienne; 20 miles S.E. of Confolent.

COGNATION, in the *Civil Law*, the bond of relation between all the descendants of the same stock, both males and females; by which it is distinguished from *agnation*, which only comprehends the descendants of the male sex.

In France, for the succession of the crown, they follow *agnation*; in England, Spain, &c. *cognation*; women coming to the succession, according to the degree of proximity, in default of males, or their descendants from branch to branch.

In the *Roman Law*, the words *cognatio* and *cognati* are also taken in a more limited sense; *cognatio* signifying only the bond of relation between the descendants from the same stock by women; and *cognati* those between whom there was such a bond of relation subsisting.

COGNE, in *Geography*, a valley of Piedmont, belonging to the bishop of Aosta, so called from the small river which waters it. The mountains, by which it is surrounded, are rich in mines of iron and copper. It contains 13 villages, the chief of which is Cogne; 6 miles distant from Aosta.

COGNI, in *Ancient Geography*, a people of Germany, according to Ptolemy.

COGNI, or KONIEH, in *Geography*, a town of Asiatic Turkey, the capital of Caramania, the ordinary residence of a beglerbeg, situated in a beautiful and fertile country. It is very large, and its walls are supported by 108 square towers, at the distance of 40 paces from each other. It has two considerable fauxbourgs, into one of which the caravans and strangers retire. All the inhabitants are Turks, Armenians, Jews, and others, who come hither to trade, and lodge in the khans, where they are supplied with all necessaries. Cogni is the see of a bishop;

260 miles S.E. of Constantinople. N. lat. 38° 13′. E. long. 50° 45′.

COGNIOL, in *Ichthyology*, a name given by some to the *scomber colias*, a kind of mackarel, rather smaller than the common sort, and which has the body varied with fine green and blue. It is supposed to be the young of the common mackarel.

COGNISEE, or CONNUSEE, in *Law*, is the person to whom a fine of lands, &c. is acknowledged.

COGNISOR, or CONUSOR, is he that passeth, or acknowledgeth, a fine of lands and tenements to another. See FINE, and RECOGNIZANCE.

COGNITIVE is sometimes applied to that faculty or power of the human mind, by which we know any thing, or are enabled to distinguish truth from falsity.

Latin writers use the terms *facultas cognoscitiva* in the same sense.

Hobbes has made use of the terms *cognitive* power, for the power of knowing, or conceiving, in contradistinction to *motive* power, or appetite.

COGNITIONIBUS *mittendis*, in *Law*, a writ to any of the king's justices of the common pleas, who has the power of taking a fine, and who, having taken a fine, defers to certify it, commanding him to certify the same.

COGNIZANCE, or COGNISANCE, in *Heraldry*. See C....

COGNIZANCE, or CONUSANCE, in *Law*, is the acknowledgement of a fine; or the concession of a thing done. In which sense we say *cognoscens latro*, *a thief that confesses*.

COGNIZANCE is also used for a power, or jurisdiction. Thus, *cognizance of pleas* denotes an ability to call a plea out of another court; which no one but the king can do, unless he can show a particular charter for it. See FRANCHISE.

Before defence made, if at all, cognizance of the suit must be claimed or demanded; when any person or body corporate hath the franchise, not only of *holding pleas* within a particular limited jurisdiction, but also of the *cognizance of pleas*; and that, either *without* any words exclusive of other courts, which entitle the lord of the franchise, whenever any suit that belongs to his jurisdiction is commenced in the courts of Westminster to demand cognizance thereof; or *with* such exclusive words, which also entitle the defendant to plead to the jurisdiction of the court. 2 Lord-Raym. 836. 10 Mod. 126. Upon this claim of cognizance, if allowed, all proceedings shall cease in the superior court, and the plaintiff is left at liberty to pursue his remedy in the special jurisdiction. As, when a scholar, or other privileged person, of the universities of Oxford or Cambridge, is impleaded in the courts at Westminster, for any cause of action whatsoever, unless upon a question of freehold. In these cases, by the charter of these learned bodies, confirmed by act of parliament, the chancellor and vice-chancellor may put in "a claim of cognizance," which, if made in due time and form, and with due proof of the facts alleged, is regularly allowed by the courts. It must be demanded, before full defence is made or imparlance prayed; for these are a submission to the jurisdiction of the superior court, and the delay is a *laches* in the lord of the franchise: and it will not be allowed, if it occasions a failure of justice, or if an action be brought against the person himself, who claims the franchise, unless he hath also a power in such case of making another judge. 2 Ventr. 363. Hob. 87. Yearbook, M. 8. Hen. VI. 20. 3 Comm. 298. See *University* COURT.

COGNIZANCE, notice, power, or jurisdiction. In a *military* sense or acceptation, it denotes the investigation or trial, to which any person subject to martial law, or any act of his, is liable. During the suspension of civil authority, every offence is an object of military cognizance, is subject to martial law, and may be proceeded upon according to the summary spirit and nature of its regulations.—A drum-head court-martial for instance.

COGNIZANCE is sometimes used also for an audience, or hearing of a matter judicially. In which sense we say, *to take cognizance*, &c.

COGNIZANCE, again, is used for a badge on a waterman's, or servingman's sleeve, which is commonly the giver's crest, whereby he is discerned to belong to this or that nobleman, or gentleman.

COGNIZANCE, &c. *fine Sur*, &c. See FINE.

COGNIZANCE in *replevin*. See REPLEVIN.

COGNOMEN, in *Roman Antiquity*, a name that was peculiar to some family, or more properly to some branch of that family. The cognomen, which originally was often a kind of nick-name, or on the contrary an appellation of honour, distinguished the different branches of the same house, "in eadem gente;" as when Livy says (l. 9. c. 29.), that the house of the Potitii was divided into 12 families. See NAME.

COGNOVIT *actionem*, in *Law*, is where a defendant acknowledges or confesses the plaintiff's cause against him to be just and true; and before or after issue, suffers judgment to be entered against him without trial. Here the confession generally extends no farther than to what is contained in the declaration; but if the defendant will confess more, he may. 1 Rol. 929. Hob. 178. See JUDGMENT. But frequently the defendant confesses one part of the complaint, and traverses or denies the rest.

COGOLLA, in *Geography*, a river of Spain, which runs into the Nagarella, in the country of Rioja.

COGOLLUDO, a town of Spain, in New Castile; 20 miles W. of Siguença.

COGORETO, or COGURETO, a village of Italy, on the coast of Genoa, remarkable for being the native place of Christopher Columbus, the discoverer of America.

COGOXIMA. See CANGOXIMA.

COGS. See COGGLE.

COGWARE is said to be a sort of coarse cloths, made in divers parts of England, of which mention is made in 13 R. II. c. 10.

CO-HABITATION, implies a concubinage, copulation, or carnal knowledge, between two persons. It is rarely used, except in a criminal sense.

COHALA, in *Geography*, a stationary tribe of Arabs in Abyssinia, who do not live in tents, but are tributary to the mek, occupying different districts of Sennaar, near the river Rahad, and regularly paying all the taxes and exactions which are imposed by the government of Sennaar.

COHASSET, a township of America in the county of Norfolk, and state of Massachusetts, incorporated in 1770, and containing 817 inhabitants. It has a congregational church, and includes 126 houses, scattered in different forms. The dangerous rocks of this name lie off this place, about a league from the shore. It is distant about 25 miles S. E. from Boston, or in a straight line about half of this distance.

COHAUSEN, JOHN HENRY, in *Biography*, a learned and ingenious physician, was born at Hildesheim in Lower Saxony, towards the end of the seventeenth century. Being educated to the practice of medicine, after taking the degree of doctor, he went to Munster, where he soon distinguished himself, by his superior skill and abilities. His works, which are numerous, bear ample testimony to the vigour of his intellects, and of his application to letters. His last work, "Hermippus Redivivus," in which he professes to shew the practicability of prolonging the lives of elderly persons to 115 years, by receiving the breath, and transpirations of healthy young females, was written, or first published, when he was in his 77th year. This was translated into English, and published, with additions and improvements, by the late Dr. John Campbell, under the title of "Hermippus Redivivus, or the Sage's triumph over old Age and the Grave." A vein of humour runs through this, and indeed through most of the productions of this writer, which gave them great popularity when first published, though they are now little noticed, excepting, perhaps, the work just mentioned, in which the irony is extremely delicate, and his rhapsody, against the prevailing passion of taking snuff. He affects to consider a passion for taking snuff as a disease of the nostrils, similar to that affecting the stomach of girls in chlorosis, and therefore calls it the pica nasi. The title of this production is, "Dissertatio Satyrica, physico-medico-moralis, de Pica Nasi sive Tabaci sternutatorii moderno abusu, et noxa." Amstelodami, 1716, [illegible].

Ruysch, in the latter part of his life, imagined he had discovered a muscle at the fundus uteri, to which he delegated the office of expelling the placenta, and to which he thought the performance of that duty might be left. This our author has ridiculed in a little volume, to which he gave the title of "Lucina Ruyschiana, sive musculus uteri orbicularis a clarissimo, D. D. Ruyschio detectus," published at Amsterdam, 1731. The following is a specimen of the author's humour on the occasion:

"Vos obstetrices manum a placenta;
Nolite illam, si reluctetur, tangere.
Adest expulsor musculus,
Qui illam, mechanicis suis digitis, extrahet,
Et molem inutilem ejiciat, destinato tempore;
Si fata volent."
And further on,
"Vos obstetrices, si fætum extraxeritis,
Resistat autem placenta.
Ite nunc domum, haud anxiæ,
An mors, an alia symtomata illam retentam sequantur,
Modo utero vim nullam intuleritis.
Musculus orbicularis vestras vices
supplebit,
Et placentam indubitatò, ni fallimur, extrahet.
Quid ad vos, si hic suo officio
non fungatur?
Ovos, nunc tali invento musculo, felices!
Vos fæminæ decumanis laudibus mactate
Magnum Ruyschium,
Quod salutis vestræ mysterium non celarit, obstetrices."

He published the preceding year, "Archæus faber febrium et Medicus," and in 1716, "Neothea," written to shew the folly of sending to China for tea, when we have so many herbs at hand, as pleasant, and more healthy; but his wit was not powerful enough to make either the use of tea or tobacco unfashionable. For the titles of others of his works, see Boerhaave's Methodus Studii Medici. Cohausen died at Munster, July 18th, 1750, in the 85th year of his age.

COHÁWSY or Cæsaria, in *Geography*, a small river of North America, which rises in the county of Salem, in the state of New Jersey, and pursuing its course through Cumberland county, discharges itself into Delaware river, opposite to the upper end of Bombay Hook. It is about 30 miles in length, and is navigable for vessels of 100 tons to Bridgetown, at the distance of 20 miles from its mouth.

CO-HEIR, a person who shares an inheritance or estate with another heir.

COHEL, a name given in Egypt to a preparation of tin burnt with gall-nuts, which the Turkish women make use of to blacken, and lengthen their eye-brows.

COHERENCE, a school-term, applied to propositions, discourses, &c. which have a mutual connection, or dependance on one another.

COHESION, compounded of the particle *co*, with or together, and the verb *hærere*, to stick, in *Philosophy*, means that action or power, by which the homogeneous particles of bodies remain attached to each other, as if they were but one; thus the particles of gold, or of mercury, or even of water, &c. cohere together; nor can they be separated without employing a degree of force, which must be different not only in different bodies, but likewise in the same body under different circumstances. This same power of cohesion, between the homogeneous particles of matter, is called, by the chemists, the *attraction of aggregation*. The philosophical writers have generally annexed the same meaning to the words *adhesion* and *cohesion*; we have, however, for distinction sake, used the former in a sense somewhat different from the latter, and this difference has already been stated under the article Adhesion.

In contemplating the power of cohesion, two different particulars present themselves for our examination; namely, the facts which have been experimentally ascertained relatively to it, and the theories which have been offered in explanation of those facts.

The various bodies of the universe, when considered with respect to the connection of their particles, are distinguished into solids, fluids, and elastic fluids. The particles of the solids cohere with a very great power; whilst those of the elastic fluids, instead of cohering, repel each other. The fluids, like water or alcohol, are in an intermediate state, *viz.* their component particles slightly cohere, at the same time that, when exposed, they are continually evaporating, that is, assuming the elastic, or vaporous form.

Several bodies have been found to assume all the abovementioned states, according as they are more or less combined with caloric, or the matter of heat. Thus water is a solid below the temperature of 32°, is a fluid between the temperatures of 32° and 212°; and becomes an elastic fluid when heated beyond the last mentioned degree. Abstract the heat, and the vapour gradually becomes a fluid, and this fluid becomes a solid, *viz.* ice. The like transition of state has been observed in various other bodies; hence we are induced, from analogy, to conclude, that, were it in our power to deprive every substance of all its heat, the whole range of natural bodies, including even the aërial fluid, might be converted into solids.

Besides heat, there is another power which weakens the cohesion of the homogeneous particles of bodies, and this is the attraction between the particles of different sorts of matter. Thus, a solid salt, when put in water, is dissolved, *viz.* its particles are separated from each other, in virtue of the attraction between them and the particles of water. Remove the water by means of evaporation, and the particles of salt will again cohere into a solid form. This is called by the chemists, *the attraction of affinity*, and the very extensive series of chemical phenomena, depends principally, if not entirely, upon the various affinities of natural bodies. See Chemical Affinity.

It appears, therefore, that the homogeneous particles of every sort of matter, have a mutual tendency towards one another,

another, in consequence of which they cohere more or less powerfully, according as that power is counteracted in a lesser or greater degree, either by the interference of heat, or by the affinity to other bodies, namely, the chemical affinity. And the effect is much more remarkable when both those powers act at the same time. Strictly speaking, the action of heat ought to be included in the general name of chemical affinity.

Independent of the actual interference of the two abovementioned counteracting powers, the particles of the same kind of matter will cohere with various degrees of force, according as they have been permitted to descend from the soft, or fluid state, to the solid form, either gradually or abruptly; which clearly indicates a sort of polarity in the particles, that is, a tendency to arrange themselves in one particular manner, rather than in any other, in order to cohere more powerfully; and hence arise several qualities of the same solid, *viz.* tenacity, elasticity, rigidity, transparency, regularity of form, commonly called crystallization, &c. Thus, if the aqueous part of a saline solution, and the heat, be caused to escape suddenly, the salt will be left in a pulverized form, whose particles shew a slight adhesion, if any, to one another. But let the water and the heat escape very gradually, and the particles of the salt will arrange themselves, so as to form regular bodies, called crystals, of considerable size, hardness, and transparency. Thus likewise, if a piece of steel be made red hot, and be afterwards cooled gradually, it will remain pretty soft and pliable; but if it be cooled suddenly, as by plunging it in water, and especially in quicksilver, the piece of steel will afterwards be found very hard and brittle, so much so that a file will have no action upon it.

It is hardly necessary to add any proofs of the existence of the above-mentioned cohesive power, since common experience shows, how two drops of water, or of quicksilver, or of any other fluid, rush together when they are barely brought to touch in some small part of their surfaces; how a drop of a fluid endeavours to assume a globular form, in consequence of the mutual attraction of its particles; how the motion of a solid in a fluid is retarded by the cohesion between the particles of the latter; how difficult it is to break a metallic rod, or any other solid, &c.

Take two leaden bullets, such as are used for muskets, scrape off a part of each, so as to form two small plain and bright surfaces, apply these to each other, bringing the parts close by compression, and a little twist with your fingers. Now these bullets will be found to adhere very forcibly to each other, so as to require a strong power (equivalent sometimes to the weight of 5, or 6, or 8, or even more pounds), in order to separate them. When separated, the surfaces will no longer appear flat; for part of the metal of one bullet seems to be intimately fastened to the other. This experiment will not answer in the same manner when harder metallic bodies are employed.

The knowledge of the tenacity of bodies is of great consequence in civil economy, and especially in the mechanical arts; hence several experiments have been instituted for this purpose; yet it is to be wished that the performance of a greater variety of such experiments, under the various circumstances which affect the strength and tenacity of bodies, *viz.* the various temperature, size, and other qualities, were undertaken by persons of knowledge and ability, in order to render the use of natural bodies in mechanics, and other useful branches, more certain and determinate. Professor Muschenbroeck made and published a greater number of experiments, for determining the cohesion of various substances, than any other philosophical writer. They do not all relate to bodies of an homogeneous nature; for he tried likewise the cohesion, or strength of different sorts of wood, which are composed of earthy, saline, resinous, and various other particles. We shall, however, transcribe them all together, as they form a very useful collection of results, relative to the strength of various bodies.

P. Muschenbroeck, in order to try the cohesive power of two polished planes, took two lumps of the same substance, such as glass and glass, copper and copper, &c. he flattened and polished a part of each, and adapted those surfaces to each other, by the interposition of some soft substance which might exclude the air; then, having fastened one of those pieces to a firm stand, he appended weights to the other, until the planes were separated from each other, and noted the weights which effected the separation. When the polished planes were about two inches in diameter, the pieces were heated in boiling water, in order to melt a little grease that was interposed between the polished planes. Two lumps of glass, or brass, &c. thus prepared, were separated by the weights expressed in the following table:

	Cold grease.	Hot grease.
Planes of glass, -	130 lb. -	300 lb.
brass, -	150 -	800
copper, -	200 -	850
marble, -	225 -	600
silver, -	150 -	250
iron, -	300 -	950

When the brass planes were made to adhere by the interposition of other substances, the results were as follow:

With water, -	12 oz. to separate them.
oil, -	18
Venice turpentine,	24
candle tallow, -	800
resin, -	850
pitch, -	1400

To ascertain the absolute cohesion of solid pieces of wood, he used pieces in the shape of long square parallelopipedons, each of whose sides was 0.26 of an inch, and they were broken by the following weights, which were applied in the direction of their length:

Fir, -	600 lb.
Elm, -	950
Alder, -	1000
Linden-tree, -	1000
Oak, -	1150
Beech, -	1250
Ash, -	1250

He tried likewise wires of different metals, by appending weights in the direction of their length, until they parted. The diameter of each wire was equal to 0.1 of a Rhinland inch (equal to 0.09712 of an inch English). The result were as follows:

Lead -	29¼ lb.
Tin - -	40¼
Copper -	299¼
Yellow brass -	360
Silver - -	370
Iron - -	450
Gold -	500

In order to try the transverse cohesion of different sorts of wood, or when the force acted in a direction perpendicular to their length, he fixed one of the ends of the pieces, (which were similar to those mentioned above) into a square hole in a metal plate, and hung weights on the other end, sufficient

ficient to break each piece at the faid hole. The weights and diftances from the hole were as follow:

Pieces of Wood.	Diftances.	Weights.
Fir	9 inches.	40 oz.
Oak	$8\frac{1}{2}$	48
Elm	9	44
Pine	$9\frac{1}{2}$	$36\frac{1}{2}$
Alder	$9\frac{1}{2}$	48
Beech	7	$56\frac{1}{2}$

See Mufchenbroek's Introductio ad Cohærentiam Corporum firmorum apud Phyficæ Exper. et Geom. Differtationes; and Introductio ad Philof. Nat. 4to. ed. 1762. tom. i. cap. 21.

Mr. Emerfon likewife performed feveral experiments refpecting the fame fubject, to which he fubjoined fome judicious obfervations. See his Principles of Mechanics, the latter end of the 7th fection; where he expreffes himfelf in the following manner:

"The proportion of the ftrength of feveral forts of wood, and other bodies, that I have tried, will appear in the following table:

" Box, yew, plum tree, oak	11
Elm, afh	$8\frac{1}{2}$
Walnut, thorn	$7\frac{1}{2}$
Red fir, holly, elder, plane, crab tree, apple tree	7
Beech, cherry tree, hazle	$6\frac{2}{3}$
Alder, afp, birch, white fir, willow or faugh	6
Iron	107
Brafs	50
Bone	22
Lead	$6\frac{1}{2}$
Fine free ftone	1

"In this table I have put feveral forts of wood into one clafs together, which I found to be pretty nearly of the fame ftrength; as I found fometimes one fort to exceed in ftrength, and fometimes another; there being a great difference even in the fame fort of wood; and I don't doubt but other people that fhall make experiments, will find them as different and various as I have done, and perhaps, quite different from mine, juft according to the goodnefs or badnefs of the wood they ufe. But I have contented myfelf to fet down what I found from my own experience, as the refult of a great many trials, without any regard to what other people have done or may do. What I fhall further add is this:

"A cylindric rod of good clean fir, of an inch circumference, drawn in length, will bear at the extremity, 400lb.; and a fpear of fir two inches diameter, will bear about feven ton; but not more.

"A rod of good iron of an inch circumference, will bear near three ton weight.

"A good hempen rope of an inch circumference, will bear 1000lb. at the extremity.

"All this fuppofes thefe bodies to be found and good throughout, but none of thefe fhould be put to bear more than a third or fourth part of that weight, efpecially for any length of time."

The late Dr. Crawford, a gentleman well known for his excellent publication on elementary heat, once undertook a feries of experiments for the purpofe of determining the various degrees of force requifite to break metallic wires in different degrees of temperature; but his premature death prevented the accomplifhment of his experiments; nor does it appear, that the refult of thofe few which he lived to perform, was ever made public. He heated the wires in a cylindrical veffel full of oil.

Having ftated the particulars that have been afcertained experimentally concerning the power of cohefion; we fhall now make a fhort excurfion into the region of fuppofition and hypothefis; briefly mentioning fome of the ideas that have been entertained refpecting the caufes of thofe phenomena. The abfurdity of moft of thofe fuppofitions, and the infufficiency of others, render them undeferving of any ferious confideration. Amongft the moft enlightened philofophers who have confidered the fubject, fome have attributed the cohefion of the particles, &c. to an immaterial power; others, with J. Bernoulli at their head, have attributed it to the external preffure of the aërial, or an etherial, atmofphere. (See J. Bernouilli De Gravitate Ætheris.) The firft of thefe fuppofitions is utterly unintelligible; the fecond, when brought to the teft of experiment and computation, is found to be utterly inadequate to the effect. Sir Ifaac Newton, without attempting to inveftigate the nature of the power, judicioufly contents himfelf with calling it a mutual attraction peculiar to the particles of matter. His words are as follow:

"The particles of all hard homogeneous bodies, which touch one another, cohere with a good force; to account for which fome philofophers have recourfe to a kind of hooked atoms, which, in effect, is nothing elfe but to beg the thing in queftion. Others imagine, that the particles of bodies are connected by reft, *i. e.* in effect, by nothing at all; and others by confpiring motions, *i. e.* by a relative reft among themfelves. For myfelf, it rather appears to me, that the particles of bodies cohere by an attractive force, whereby they tend mutually towards each other; which force, in the very point of contact, is very great; at little diftances is lefs; and at a little farther diftance is quite infenfible."

But what fort of attraction can this be, which decreafes and vanifhes at diftances fo very fmall?—Break a glafs rod, then apply the parts to each other as clofe as you will, fo that the fracture can hardly be difcerned; yet the adhefion is infenfible. Defaguliers, without giving any proof of the fact, conjectures, that the cohefive power decreafes in the ratio of the fourth power of the increafed diftance; fo that at twice the diftance, it acts 16 times weaker; at three times the diftance it acts 81 times weaker, and fo forth. That a power (like the attraction of gravitation,) fhould decreafe according to the fquares of the diftances, may be eafily comprehended; it being demonftratively true, that all powers or emanations, which proceed from a centre, and expand always fpherically, muft become more and more rare, in the proportion of the fquares of the diftances from the centre of emanation. But it is extremely difficult to form any idea of a power that decreafes in the ratio of the fourth, or any higher power of the diftances.

When every thing is duly confidered, it appears much more rational to fuppofe, that each particle of matter is endowed with a polarity analogous to that of a magnet, *viz.* that with one of its fides or ends, a particle of matter can attract the fame end of another particle, but that it will repel it with its oppofite fide or end. This, as has been obferved above, feems to be indicated by a variety of phenomena; and it may be eafily illuftrated by a magnetic experiment. Take, for inftance, four or fix magnetic bars, or needles, place them fo that all their poles of the fame name may lie on one fide, and you will find, that inftead of attracting, they will repel each other; fecondly, place them fo that two or three north poles may be together with one fouth pole, on one fide, and the attraction between the bars will be flight or partial. Laftly, place them in regular order, fo that the north pole of one bar may be contiguous to the fouth pole of the next, and that to the north pole of a third bar, and fo forth; and you

you will find that the bars cohere with confiderable force. Upon this hypothefis, the above-mentioned experiment of the broken glafs rod may be explained in a more fatisfactory manner; for though the fractured parts may appear to be replaced in their original fituation; yet it is fcarcely poffible to attain that immenfe accuracy, which is required to difpofe the friendly poles or ends of the minute particles contiguous to each other. The leaft abrafion of furface, the leaft interpofition of any matter, deranges the whole. Upon this hypothefis it is alfo eafy to comprehend how the different hardnefs and configuration of the fame kind of body are produced; for when the particles are fuddenly depofited from any folution, or fuffer a quick tranfition from the foft to the hard ftate, they have no time to arrange themfelves in the proper order; confequently the aggregate becomes lefs compact and irregular, than when by a flow depofition, or gradual tranfition from the foft to the hard ftate, fufficient time is allowed for the particles of matter to place themfelves in their proper fituations.

COHIBUS, fo called by Tacitus, but by Arrian *Chôbus*, in *Ancient Geography*, a river of Afia near the Euxine fea.

COHOBATION, in *Chemiftry*, is the repeated expofure of any fubftance to the chemical action of a liquid, either by returning the latter when driven off by diftillation, or by fupplying a frefh quantity after the action of the firft has been exhaufted.

CO-HONG, in *Geography*, a town of Afia in Thibet; 20 miles S.W. of Tfien-tfang.

COHONGORONTO, the name of the American river Potowmack, before it breaks through the Blue Ridge in N. lat. 39° 45'. Its whole length to this place is about 160 miles.

COHORN, MEMNON, in *Biography*, a celebrated engineer in Holland, the ftrong places of which are generally indebted to him for their fortifications. At the fiege of Namur, he defended a fort, named after himfelf, againft the attack of Vauban. Cohorn refufed to furrender till he had received a wound, which was deemed mortal at the time, but from the effects of which he recovered. In 1703, the elector of Cologne, efpoufing the caufe of France, admitted a French garrifon into Bonn; Cohorn attacked the place with fo much vigour, that the commandant furrendered in three days. He died the following year at the Hague, leaving behind him a treatife on his method of fortification. Nouv. Hift. Dict. Du Frefnoy.

COHORS *equitata*, in old infcriptions, has perplexed feveral antiquaries, who have been taught to confider the *cohorts* as appropriated to the foot fervice, as the *alæ* and *turmæ* were to the horfe. Mr. Horfeley, in particular, imagines, the *cohors prima Claudia equitata*, which he had met with, was intended to intimate that this cohort had been promoted from the horfe fervice; but when, by another infcription, he was led to confider that corps as confifting of a thoufand horfe, his difficulty is increafed to that degree, that he knows not what to affirm upon it. But the learned Dr. Taylor thinks there is an eafy folution of this difficulty.

The auxiliary, or provincial cohorts, were either entirely, or purely foot, like the legionary, or ordinary *cohorts*; or elfe they had a mixture of both kinds of militia, as appears from Gruter, Dlxxiv. 5. This latter fort, as they could not properly be ranked under either denomination of horfe, or foot, being made up of both, feem to have appropriated to themfelves the diftinguifhing title of *cohortes equitatæ*, corps of infantry with a mixture of horfe. And of this term we find frequent mention in infcriptions.

Hyginus alfo, "De Caftrametatione," gives us a full and decifive proof of this denomination, and of the number of which fuch cohorts confifted. Thefe troops confifted of a thoufand men, part horfe, and part foot, and were hence called *milliariæ*. The proportion of the horfe to the foot was 240 to 760. His words are, "Habet *cohors equitata* milliaria pedites feptingentos fexaginta, centurias decem, equites ducentos quadraginta, turmas decem." Vid. Phil. Tranf. N° 482. fect. 3.

COHORS *milliaria*. See above COHORS *equitata*.

COHORT, COHORS, in *Roman Antiquity*, a body of infantry, confifting of five or fix hundred men; anfwering in moft refpects to our *battalion*.

The cohort was divided into three manipules, or companies; the manipule into two centuries; and the century into an hundred men.

The firft centurion in the firft cohort was called *primipilus*; and had the charge of the eagle or ftandard of the legion. —A legion confifted of ten cohorts. The firft cohort, which always claimed the poft of honour, was formed of 1105 foldiers, the moft approved for valour and fidelity. The remaining nine cohorts confifted each of 555. See LEGION.

When the army was ranged in order of battle, the cohorts were difpofed in the following manner: The firft cohort took up the right of the firft line, as the companies of grenadiers do in our regiments; the reft followed in their natural order; fo that the third was in the centre of the firft line of the legion, and the fifth on the left; the fecond between the firft and third; and the fourth between the third and fifth. The five remaining cohorts formed a fecond line in their natural order: thus the fixth was behind the firft, and fo of the reft.

The firft, third, and fifth cohorts were efteemed the beft; at leaft it appears fo from the pofts they took up, which were looked on by the Romans as the moft important.

Marius is by fome faid to have been the firft who divided the Roman forces into cohorts: which opinion feems confirmed by Rofinus; "Non enim in tota Livii hiftoria cohortium fit mentio. Ideoque docti viri fentiunt a C. Mario primum cohortes effe inftitutas." But yet this is a great miftake; for the cohorts are often mentioned in Livy, and particularly, lib. xxvii.; c. 13. "Marcellus—cohortibus quæ figna amiferant hordeum dari juffit: centurionefque manipulorum quorum figna amiffa fuerant diftrictis gladiis diftinctos deftituit." This happened A. U. C. 543, and confequently feveral years before Marius was born. *Cohorts* were diftinguifhed according to their appointment and office, into *auxiliary*, which were fent by allies; *equitata*; fee above; *peditata*, which confifted of foot-foldiers only; *prætorian*, which was formed of the beft foldiers, and ferved to guard the *prætor* or general. This cohort was inftituted by Publius Pofthumus, the dictator. Auguftus likewife formed a cohort under this appellation, confifting of nine thoufand men: which was afterwards increafed by Septimius Severus. There were alfo the *cohors togata*, a kind of militia, which guarded the ftreets of Rome; the *cohors vigilum*, inftituted by Auguftus, which ferved on occafion of fires; and the *cohors urbana*, eftablifhed by Auguftus, to guard the city.

COHOZ, or COHOES, in *Geography*, a fmall village of North America, near which is the remarkable fall of the Mohawk river, about three miles from its mouth, by which it difembogues itfelf into the Hudfon or North river, about ten miles above Albany. The breadth of the river is 300 yards; a ledge of rocks extends quite acrofs, and from the top of them the water falls about 50 feet perpendicular, or, as fome fay, between 70 and 80 feet; the line of the fall from one fide of the river to the other being nearly ftraight. The appearance of this fall or cafcade is very different, according to the quantity of water; when the river

river is full, the water descends in an unbroken sheet from one bank to the other, whilst, at other times, the greater part of the rocks is left uncovered. The rocks are of a very dark colour, as is also the earth on the banks, which rise to a great height on either side. A bridge, 1100 feet long, and 24 feet wide, resting on 13 piers, was erected, at the expence of 12,000 dollars, in 1794, about three quarters of a mile below the cataract, from which it exhibits a grand view to the spectator; though the most romantic appearance is observed from Lansinburgh-hill, about five miles to the east of it.

COHUAGIUM, in *Antiquity*, a tribute paid by those who meet promiscuously in a market, or fair; *cohua* signifying a promiscuous multitude of men in a fair or market, probably from the French *cohue*.

COHUIXCAS, in *Geography*, a country of New Spain, in which there is a considerable mountain of loadstone, between Tcoiltylan and Chilapan.

COIBA, or QUIBO, a small island in the Pacific ocean, near the coast of Veragua. N. lat. 8°. W. long 82° 26′.

COIF, the badge of a serjeant at law; who is hence also called serjeant of the coif.

The coif is of lawn, and is worn on the head, under the cap, when they are created, and ever after.

The use of the coif was to cover the *tonsura clericalis*, or clerical crown; because the crown of the head was originally close shaved, and only a border of hair left around the lower part, which gave it the appearance of a crown. We have an example of its antiquity in M. Paris's "History of England," A. D. 1259, when one William de Bussy claimed the benefit of his clergy, and hence sir H. Spelman conjectures (Gloss. 355.) that coifs were introduced to hide the tonsure of such renegade clerks, as were still tempted to remain in the secular courts in the quality of advocates or judges, notwithstanding their prohibition by canon. See TONSURE, &c.

COIFFE-JAUNE, in *Ornithology*, the name given by Buffon to the *oriolus icterocephalus*.

COIFFE-*Noir*, of Buffon, is the hooded tanager; *Tanagra pileata*, Linn.

COIFFY-LA-VILLE, in *Geography*, a town of France, in the department of the Upper Marne; three miles S.W. of Bourbonne.

COIGNET, GILLES, in *Biography*, called likewise *Giles of Antwerp*, from the place of his nativity, was born in 1530, and in his youth received employment for some time in the house of Antonio Palermo, a picture merchant of that city. He afterwards travelled through the greater part of Italy and Sicily, and in many places left specimens of his abilities, as well in fresco as in oil. At Terni, a small town in the Papal territory, he painted a room entirely with whimsical grotesques, and likewise an altar picture; in this last, however, he was assisted by a scholar of his, named Stella, who afterwards died in Rome. From Italy he repaired to Amsterdam, where he painted many works highly creditable to his talents, and at last settled at Hamburgh, where he died in the year 1600. Coignet is described as an universal artist, sufficiently skilled in history, landscape, and indeed every department of painting; but his excellence was most remarkable in his small pictures of conflagrations, or where his figures were illumined by the moon, or by torches, lanthorns, or other artificial flame. He not unfrequently worked upon the copies made by his scholars, and, by means of a few masterly touches of his pencil, gave them, at first sight, so much the appearance of originals, that many were deceived. Many of the back grounds and architectural parts of Cornelius Molinaer's pictures were painted by him. Baldinucci.

COIL, denotes a rope laid in regular folds for the convenience of stowage, and hanging upon cleats, to prevent its being entangled. See QUOIL.

COILANTHA, in *Botany*. Renal. Sp. See GENTIANA *purpurea*.

COILON, in *Antiquity*. See CAVEA.

COILOPHYLLUM, in *Botany*, Moris. See SARRACENIA *purpurea*.

COILOTAPALUS, Brown. See CECROPIA *peltata*.

COILPETTA, in *Geography*, a town of Hindoostan in the Carnatic; 54 miles S.W. of Madura, and 18 N. of Palamcotta.

COIMBETORE, a province of Hindoostan, in the Mysore, and in the southern part of the territories formerly belonging to Tippoo Sultan. This country is separated from Calicut and Cochin towards the west by a ridge of lofty mountains named the "Gauts," a continuation of which bounds it on the north; on the east it is bounded by the Carnatic; and on the south by the province of Dindigul. In the continuity of the ridge of mountains on the west, opposite to Paniany, there is a break about 16 miles wide, which appears to border on what d'Anville calls "Annamally," or the "Elephant Mountains," and is occupied chiefly by a forest of timber trees, having the fort of Annamally on the east, and Palicaudcherry on the west. The valley or opening extends 14 or 15 miles between the termination of the Northern Gauts, and the commencement of the Southern ones; before it opens finally into the low country on the Malabar coast. It is well known, says major Rennell, that ships which navigate the Malabar coast during the N.E. monsoon, commonly experience a stronger gale in the neighbourhood of Paniany than elsewhere; and he is of opinion, that this opening in the Gauts is a very sufficient cause of such an effect. The major has also been told, that the lower part of the Coimbetore country partakes of the rainy, or S.W. monsoon of the Malabar coast, which may be referred to the same cause. The river of Paniany takes its course from the Coimbetore country, through this opening; and is said to be navigable in the rainy season for small boats, to the foot of the Gauts. This circumstance, together with the inundated state of the country at that season, may serve to show, that the country, west of the Gauts, has no great declivity, in a course of near 60 miles. Coimbetore is a fertile country, and well watered by several rivers; its principal towns are Coimbetore, Erroad, Carroor, and Daraporam.

COIMBETORE, a town of Hindoostan, and capital of the province to which it gives name, situated at the foot of the western Gauts, on the river Noyel. This town was taken possession of by general Meadows in July 1790, after having been evacuated by Tippoo Sultan, who left behind him a quantity of grain and military stores. The mud fort by which it was defended was incapable of making any long resistance. Tippoo retook it in the following year, and it was confirmed to him by the peace; but by the partition treaty, made by marquis Wellesley in 1799, Coimbetore, and also Sattimungalum, Erroad, Perentory, Oudcul, Showoor, Chingery, Cangiam, Carroor, Vizimungle, and Daraporam, were annexed to the British possessions. N. lat. 10° 58′. E. long. 77° 7′.

COIMBRA, a large, handsome, and celebrated city of Portugal, the capital of the province of Beira, situated on a mountain near the river Mondego, in a country abounding with vineyards, olive-trees, and fruits. It was built by the

Romans about 300 years before Chriſt. It is a biſhop's ſee, ſuffragan of Liſbon, and has an ancient univerſity, containing, according to Link, about 800 ſtudents, a cathedral, and fountains that are very magnificent. N. lat. 40° 18′. W. long. 8° 30′.

COIN, *Matrice*, in the manufacture of money, medals, and counters, is a piece of ſteel well tempered, four or five inches deep, ſquare at bottom, and round at top; whereon are engraved, dent-wiſe, with puncheons, and other inſtruments, the ſeveral figures, marks, &c. to be ſtruck on the moneys, &c. See COINAGE.

For the manner of engraving coins, ſee ENGRAVING *on ſteel*.

COIN is more generally uſed for a piece of metal, ſtamped with certain impreſſions, which are intended to give it a legal and current value; and alſo to ſerve as a guarantee for its weight and purity.

According to L. Coke, the term *coin* is French, ſignifying a corner, and hence has its name; becauſe in ancient times money was ſquare, with corners. 1 Inſt. 297. Others derive it, by a kind of forced analogy, from the Greek κοινος, *common*, becauſe money is the common medium or inſtrument of commerce. Others again deduce it from *cuneus*, a wedge, tracing its origin either to the form of a wedge, ingot, or lingot (linguetta), in which bullion has been tranſported from the remoteſt ages; or to the wedge, or chiſſel, an inſtrument with which theſe lingots were occaſionally cut to the weight required, as they do at this day in the Eaſt Indies with ſheers.

Coins conſtitute the ſtandard or ſcale, by which the prices of all things bought and ſold are aſcertained. See MONEY, CURRENCY, and COMMERCE.

Coin differs from money, as the ſpecies from the genus. Money is any matter to which public authority has affixed a value, and which ſerves as a circulating medium, whether it be metal, paper, leather, ſhells, &c.; but coin is a particular ſpecies of money, always made of metal, and ſtruck according to a certain proceſs. See COINAGE.

The origin of coins, like that of moſt other uſeful things, is involved in great obſcurity. Whether coins be of equal antiquity with money, may admit of ſome doubt; eſpecially as moſt of the ancient writers are ſo frequent and expreſs in their mention of leathern money, paper money, wooden money, &c. Some, however, notwithſtanding all this, are of opinion, that the firſt moneys were of metal; the reaſons they give are the firmneſs, neatneſs, cleanlineſs, durableneſs, and univerſality of metals; which, however, do rather conclude, that they ought to have been ſo, than they actually were ſo.

In effect, the very commodities themſelves were the firſt moneys, *i. e.* they were current for one another by way of exchange; and it was the difficulty of cutting, or dividing certain commodities, and the impoſſibility of doing it without great loſs, that firſt put men on the expedient of a general medium.

Indeed, thus much may be ſaid in behalf of coins, that, on this view, it was natural for men to have their firſt recourſe to metals, as being almoſt the only things whoſe goodneſs, and as it were integrity, is not diminiſhed by partition; beſides the advantages above expreſſed, and the conveniences of melting, and returning them again into a maſs of any ſize or weight.

It was probably, then, this property of metals which firſt accuſtomed people, who trafficked together, to account them in lieu of quantities of other merchandizes in their exchanges, and at length to ſubſtitute them wholly in their ſtead; and thus aroſe money; as it was their other property to preſerve any mark or impreſſion a long time, which confirmed them in the right; and thus was the firſt riſe of coins.

In the firſt ages, it is probable, that each perſon cut his metal into pieces of different ſizes and forms, according to the quantity to be given for any merchandize, or according to the demand of the ſeller, or the quantity ſtipulated between them; to this end they went to market, loaden with metal, in proportion to the purchaſe to be made, and furniſhed with inſtruments for proportioning it, and with ſcales for dealing it out, according as occaſion required.

By degrees it was found more commodious to have pieces ready weighed; and as there were different weights required, according to the value of the different wares, all thoſe of the ſame weight began to be diſtinguiſhed by the ſame mark, or figure; thus were coins carried one ſtep further.

At length, the growing commerce of money beginning to be diſturbed with frauds, both in the weights and the matter, the public authority interpoſed; and hence aroſe the firſt ſtamps or impreſſions of money; to which ſucceeded the names of the moneyers, and at length the effigy of the prince, the date, legend, and other precautions to prevent the alterations of the ſpecies; and thus were coins completed.

Herodotus aſcribes the invention of coins to the Lydians, and Pliny attributes it to Bacchus; but it is evidently too remote to be traced to any authentic ſource. Lycurgus ordered that iron money only ſhould be uſed at Sparta, which ſeems to imply, that a better kind had been known; and the introduction of copper coin into Italy, is aſcribed to Janus, or Saturn. We learn, however, from Pliny, and other good authorities, that ſilver was not coined at Rome until about the year 480 of the city, nor gold until about the year 640.

We do not find in Scripture that any coins were ſtruck by the Jews, until the time of the Maccabees; their money, before that period, being pieces of ſilver, of certain weights, ſuch as ſhekels, talents, and drams; a practice ſtill retained in China, and other countries; and which appears to have been univerſal in ancient commerce. It may be, therefore, preſumed, that when thoſe weights became altered and diſturbed by fraud, the neceſſity of ſtamping them with certain impreſſions became obvious; and hence may be ſuppoſed the origin of coins, with their effigies, legends, dates, &c. for which ſee MEDALS.

Coins have been generally made in all civilized nations, either of gold, ſilver, or copper, and frequently of all three: theſe metals have been found by long experience the fitteſt materials for money, particularly the two former, which we ſhall chiefly notice in the preſent article.

Gold and ſilver are each perfectly homogeneous, from whatever mines they may have been taken. Theſe metals are likewiſe malleable, and diviſible, into the moſt accurate proportions; from their ſcarcity and price, they are not too bulky for the common purpoſes of commerce; and, from their durability, they are leſs ſubject to decay than moſt other articles of value.

Gold and ſilver, in their pure or unmixed ſtate, are too flexible to make coins ſufficiently firm for general uſe; and hence the neceſſity of mixing with them a certain proportion of ſome harder metal; and this mixture is called the *alloy*. The quantity or proportion of alloy is various in different countries, and has varied conſiderably in different ages. Arbuthnot (ch. 6.) ſtates, that the ancient coins, particularly of gold, had very little alloy, in ſome not above a fiftieth part. The Romans, according to Paucton, were the firſt who taught the world the criminal art, as he calls it, of debaſing the purity of metals intended for coins, (ſee "Metrologie," p. 329.) Pliny informs us (lib. xxxiii. ch. 3.) that the Romans mixed an eighth part of alloy with their

 ſilver

ſilver coin. "Livius Druſus in tribunatu plebis octavam partem æris argento miſcuit." The ſame author thus notices their illegal debaſement of money: "Miſcuit denario triumvir Antonius ferrum. Miſcuit æri falſæ monetæ." (lib. xxxiii. c. 9.)

The quality of alloy has been always conſidered of importance with reſpect to the durability of coins. The moſt common ſort is copper; and ſometimes for gold a mixture of ſilver and copper. In order to aſcertain the beſt kind of alloy for gold coins, a chemical proceſs was inſtituted in London in 1798, under the management of Henry Cavendiſh, eſq. F.R.S., and Charles Hatchet, eſq. F.R.S.; and the reſult of their experiments was, that gold coins are not ſo likely to wear by abraſion and friction, if they are alloyed with ſilver and copper, as with copper only; but that the difference between them, provided the copper be very pure, is ſo little, that there is no ſufficient reaſon for altering the preſent alloy, conſiſting alone of copper. The report of this ingenious and elaborate proceſs, may be ſeen in the Philoſophical Tranſactions for 1803.

In all well regulated governments, there has been a ſtandard for coins, fixed by law; that is, a certain proportion between the quantity of pure metal and its alloy. In England the ſtandard for gold is $\frac{11}{12}$, that is 11 parts of pure metal, and one part of alloy. The fineneſs of gold is moſtly expreſſed in carats; thus the whole weight is ſuppoſed to be divided into 24 equal parts, called carats, and the ſtandard for gold is ſaid to be 22 carats fine, that is to contain 22 parts of pure gold, and 2 of alloy, which gives $\frac{22}{24}$. or $\frac{11}{12}$. The Engliſh carat is divided into 4 parts, called grains.

The ſtandard for ſilver is $\frac{37}{40}$, that is, 11 oz. 2 dwts. of pure ſilver, and 18 dwts. of alloy, making together 1 lb. troy, which may be thus expreſſed, $\frac{222}{240} = \frac{37}{40}$. This proportion for ſilver is ſaid to have been fixed in the reign of Richard I., by certain perſons from the eaſtern parts of Germany, called *eaſterlings;* and hence the word *ſterling*, which was afterwards the name given to the ſilver penny, and which is now applied to all lawful money of Great Britain.

From the legal weight and fineneſs of coins, there is a certain allowance for deviation or error, according to the mint regulations of moſt countries; and this allowance is called the *remedy of the mint*. In England, the remedy for gold is the ſixth part of a carat, that is, the piece coined may fall the 144th part ſhort of its ſtandard weight and fineneſs; and the remedy for ſilver is 2 dwts. in the pound, that is, the 120th part of the ſtandard. In ſome countries, a certain remedy is allowed in the weight, and another in the fineneſs; and this allowance is often made a ſource of profit, beſides the ſeigneurage; but, according to our mint indentures, the remedy is only an allowance for accidental error; and, therefore, no account is taken of it in calculating the value of our coins. It may be here obſerved, that in England there is no ſeigneurage, or other advantage, derived from the privilege of coining, the whole expence of the mint being defrayed by the public. On the propriety, however, of this regulation, the ableſt politicians have differed; and there is a probability, that in the new coinage which is now in contemplation, a ſeigneurage will be eſtabliſhed, particularly in the ſilver and copper coins, which chiefly regard our internal traffic; but as foreign bills of exchange ſhould be always paid in gold coin of full value, no great change is likely to take place in this reſpect.

According to our preſent mint regulations, whoever takes a quantity of ſtandard bullion to the tower, whether gold or ſilver, will receive in return his full weight in new coins, in the following proportions: For every pound troy of ſtandard gold, he will receive $44\frac{1}{2}$ guineas; and for every pound troy of ſtandard ſilver, 62 ſhillings. This regulation for ſilver, commenced in the reign of queen Elizabeth; and that for gold in the reign of Charles II.; the ſhilling always paſſed for 12 pence; but when the guinea was firſt ſtruck, it paſſed for about 20 ſhillings; but its value was not abſolutely fixed, being left to find its level, according to the market price of gold; and thus the guinea continued to fluctuate between 20 and 21 ſhillings, until the year 1728, when it was ordered to paſs current in all payments for 21 ſhillings; and this law had the effect of making gold a ſtandard, or meaſure of value, as well as ſilver.

From the foregoing regulation, it is obvious that the mint price of gold is 3*l.* 17*s.* 10*d.*$\frac{1}{2}$ per ounce, and the mint price of ſilver 62*d.* per ounce: for

As 12 *oz.* : 46*l.* 14*s.* 6*d.* :: 1 *oz.* : 3*l.* 17*s.* 10*d.*$\frac{1}{2}$; and
As 12 *oz.* : 62*s.* :: 1 *oz.* : 62*d.*

It alſo follows that the guinea ſhould weigh $129\frac{30}{89}$ grains of ſtandard gold, or $118\frac{58}{89}$ grains of pure gold; and that the ſhilling ſhould weigh $92\frac{28}{31}$ grains of ſtandard ſilver, or $85\frac{29}{31}$ grains of pure ſilver; for

As $44\frac{1}{2}$ grains : 1 *lb.* :: 1 *guinea* : $129\frac{30}{89}$ grains.
And as 24 carats : 22 carats :: $129\frac{30}{89}$: $118\frac{58}{89}$.
And for ſilver
As 62*s.* : 1 *lb.* :: 1*s.* : $92\frac{28}{31}$ grains.
And as 40 : 37 :: $92\frac{28}{31}$: $85\frac{29}{31}$.

From theſe proportions it appears, that the relative value between pure gold and pure ſilver is as $15\frac{2859}{13640}$ to 1, or as $15\frac{13}{62}$ to 1 nearly: for as $118\frac{58}{89}$: $85\frac{29}{31} \times 21$ :: 1 : $15\frac{2859}{13640}$. But the relative proportion of theſe two metals, according to the average market price for the laſt five years, is only as $14\frac{1}{2}$ to 1, as will be ſeen by the ſtatement of the prices of gold and ſilver here given.

The comparative value of gold and ſilver has fluctuated conſiderably in different ages, and in different countries. The earlieſt account we have of it is given by Herodotus, (lib. iii. p. 95.) where he ſtates the proportion to have been in Perſia, in the time of Darius, the ſon of Hyſtaſpes, as 13 to 1. Other hiſtorians ſtate, that it was as 12 to 1 in Greece, in the early periods of her hiſtory; but that about the time of Alexander the Great, it was only as 10 to 1. And this was the proportion in Rome at that period, where it continued nearly the ſame until the reign of Julius Cæſar, when, on account of the quantity of gold brought from conquered countries, it was to ſilver only as $7\frac{1}{2}$ to 1, a proportion, however, which was but temporary.

In England, from the time of the Saxons to the diſcovery of America, the relative value of gold and ſilver was about 11 to 1. In the reign of queen Elizabeth it was 13 to 1. In China and Japan in 1717, it was 9 or 10 to 1, (according to ſir Iſaac Newton's repreſentation to the lords of the treaſury at that period.) In Spain and Portugal it is, at preſent, as 16 to 1, and in moſt other parts of Europe, ſomething more than 15 to 1. Thus the extremes of fluctuation in the relative value of gold and ſilver, in all ages, may be comprehended within the limits of 17 and 7 to 1.

On a view of the Hiſtory of Coins, it appears that there has been, in general, a progreſſive reduction in their value, and that few inſtances have occurred of any advancement. The depreciation of money, in England, from the conqueſt to the beginning of the reign of Elizabeth, was occaſioned partly by the debaſement of the coin, and partly by the gradual increaſe of gold and ſilver from the mines of Europe; for the increaſe of the precious metals, like that of all other articles, tends only to diminiſh their value. From this period to the revolution a conſiderable reduction in the value of coins was occaſioned by the influx of gold and ſilver from the mines of America;

America; and from the revolution to the present time, the depreciation may be afcribed both to the increafe of the precious metals, and to the extenfive ufe of paper as a circulating medium.

The following ftatement will fhew the depreciation of our filver coin from the conqueft to the end of the reign of queen Elizabeth. But in order to make the fubject clear, it will be proper to obferve, that troy-weight was not ufed in the Englifh mint until the reign of Henry VIII. Before that period, gold and filver were weighed with what was called the Tower pound, or the moneyer's pound, which had been ufed by the Saxons, and which was lighter than the pound troy by $\frac{3}{4}$ of an ounce troy weight.

The Tower pound was coined

in the year		*s.*	*d.*		*s.*	*d.*
1066	into	20	0			
1300		20	3			
1344		22	2			
1346		22	6			
[illegible]		25	0			
1412		30	0			
1464		37	6			
1527		42	$2\frac{1}{4}$	pound troy	45	0
1560		56	3		60	0
1601		58	$1\frac{1}{2}$		62	0

The coinage of William the Conqueror was on the following fimple plan. The pound in weight and the pound in tale (*i. e.* in reckoning) were the fame. The pound in tale was divided into 20 fhillings, and each fhilling into 12 pence or fterlings; and the pound weight was divided into 12 ounces, and each ounce into 20 dwts. Thus the weight of each penny or fterling was one penny-weight, or 24 grains. This plan of coinage is faid to have been firft adopted by Charlemagne, in France, in the eighth century.

The firft Englifh gold coin of which there is any account, was ftruck in the year 1257, by order of Henry III. It was of pure gold, weighing two-pence, or fterlings of filver, and was to pafs for 20 pence. This gold pennie, as it was called, was nearly the weight of a feven fhilling piece of the prefent time, and it is faid, that "the king tried this expedient of coining gold through neceffity;" and alfo, "that the city of London made a reprefentation againft the meafure." Snelling, on Gold Coins, p. 2.

The next gold coinage was in the year 1344, when the gold florin was ftruck, which took its name from Florence, where it had firft been coined, in 1252. It was afterwards minted in moft of the countries in Europe. In Germany it was called the gulden, on account of its quality; and in Holland the guilder. The florin, however, has been long a filver coin, and in many places it is adopted as the unit in keeping accounts under an imaginary value: this, as well as all imaginary monies, had their origin in real coins, like the florin and the pound fterling.

Coin has been already defined the ftandard by which the prices of all things bought and fold are afcertained; but coin is, befides, an equivalent for which goods are exchanged; and, in this refpect, it fails as a proper ftandard, being liable to variations.

A ftandard for weight or meafures is fuppofed to be fixed; but coin, as a metal, is fubject to fluctuation in its value, like every other faleable article.

Perhaps there is no fubject of political economy fo difficult, both in theory and practice, as the proper regulation of coins. For, befides the fluctuation in price, and in the comparative value of the precious metals, coins are expofed to many other imperfections and diforders; fuch as filing, fabrication, melting, and unavoidable wear.

The imperfection arifing from the rivalfhip of gold and filver, might, it is thought, be removed, by making one metal only the meafure of property. Sir William Petty, Mr. Locke, Mr. Harris, lord Liverpool, and other writers of high authority, concur in opinion, that the coin which is the principal meafure of property, ought to be made of one metal only. But thefe authors do not agree whether it fhould be gold or filver. Mr. Locke argues that it fhould be filver, while lord Liverpool maintains, that gold has latterly conftituted the ftandard value. Thefe different opinions may be, however, in fome meafure reconciled. When Mr. Locke wrote on the fubject, filver was certainly the legal meafure of value; but in 1728, when the guinea was eftablifhed as a legal tender, gold became a meafure, and, of late years, the principal one, particularly in large payments. Indeed, while mankind continue to fet fo high a value on both metals, it is not likely that either will be exclufively adopted as a meafure of value. For the payment of bills of exchange, gold is preferred in moft countries. In Leghorn, and other parts of Italy, it has been of late years made the legal money of exchange. In fhort gold feems to be the meafure of value in great concerns, and filver in the inferior departments of bufinefs; gold may, therefore, be confidered as the integer, and filver the fraction.

It is worthy of obfervation, that the progrefs of metals, as reprefentatives of property, feems to have kept pace with the increafe of wealth and commerce. Iron, brafs, and copper, firft anfwered the purpofes of money; filver next followed; and, as property increafed, gold fucceeded. But the great increafe of riches and trade in modern times, has rendered even gold infufficient as a circulating medium, and reprefentative of property. Paper has been, therefore, fubftituted, and it is generally found the moft convenient. Where credit cannot be given, coins are neceffary; but where well founded confidence exifts, paper is certainly preferable. It is exempt from moft of the imperfections and diforders of coin; and, in many other refpects, it greatly facilitates the operations of commerce.

Among the imperfections of coin, the difference which frequently exifts between the mint and market prices of the precious metals, deferves particular notice. It has been already fhewn, that the mint price of gold is 3*l.* 17*s.* 10*d.* $\frac{1}{2}$ per ounce, and of filver 62*d.* per ounce; but the following ftatement will fhew how much the market prices have varied from thefe prices fince the year 1792, and it fhould be obferved, that for many years before that period, gold was frequently above, and feldom below, the mint price; while filver was almoft conftantly above the mint price, and higher in proportion than gold.

MARKET PRICES *of* STANDARD GOLD *and* SILVER.

MARKET

MARKET PRICES *of* STANDARD GOLD *and* SILVER
(continued.)

		Gold.	*Silver.*
	1804	4*l.* 0*s.* 0*d.*	5*s.* 6*d.*
	1805	4 0 0	5 6
	1806	4 0 0	5 8
January	1807	4 0 0	5 7
June	1807	4 0 0	5 8

From the above ftatement, it appears that, for the laft five years, the precious metals have varied very little in their value, and probably this average price will be made a rate, or rule, for the new coinage. We find here that gold has continued, during that period, at 4*l.* per ounce, which is about $2\frac{3}{4}$ per cent. above the mint price, and filver has been at an average of 5*s.* 7*d.* per ounce, which is about 8 per cent. above the mint price. It is alfo obfervable, that in the years 1800 and 1801, gold was 12 per cent., and filver 16 per cent. higher than the mint price.

While fuch a difparity exifts between the mint and market prices of the precious metals, it is manifeft that, notwithftanding the illegality of melting our coin, many of thofe which are of full weight and finenefs will be converted into bullion, when fo confiderable a profit is to be derived from the practice. Experience has too frequently fhewn that, during the excefs of the market above the mint price, our coins have difappeared; and as various inconveniencies and difficulties were occafioned by fuch fcarcity, attempts have been made to reduce the coins, particularly thofe of filver, to a deterioration adequate to the market price; and to this may, in fome meafure, be afcribed the prefent deficiency of our filver coins.

Attempts have been likewife made to reduce the gold coins, but without any confiderable effect; a laudable attention having been always paid to their weight; but it has been found impracticable to pay the fame attention to filver money; for whenever a fcarcity of it prevails, great inconvenience is experienced, in all the inferior departments of bufinefs. The public offices, therefore, and the bank, have generally connived at the debafement of our filver coins. The following was their reduced ftate in 1798, as reported by certain officers of the mint, who had been appointed to take the fame into confideration.

Deficiency	of crowns -	3 per cent.
	of half-crowns -	9 per cent.
	of fhillings -	24 per cent.
	of fixpences -	38 per cent.

Since the above period, a ftill greater deterioration has taken place, infomuch, that it is generally fuppofed our inferior filver coins at prefent are worth very little more than half their nominal value.

Among the caufes which have contributed to the depreciation of our coin, and to the advanced prices of bullion, fome reckon the reftriction, laid on the Bank of England, from paying in fpecie; a meafure which took place by order of government in 1797, and which, however, has hitherto proved falutary. But when and in what manner payment will be refumed, is a queftion of fome difficulty, as well as importance. It is obvious, from what has been already ftated, that good coins cannot be fafely iffued to any large amount, until a new rate of coinage fhall have taken place; and the prefent political ftate of Europe is another caufe that renders the continuance of the reftriction neceffary.

In the year 1798, his majefty appointed a committee of certain members of the privy council, to take into confideration the ftate of the coins of the kingdom, and the eftablifhment and conftitution of the mint, and to propofe fuch improvements, in both thefe refpects, as might to them appear neceffary. At the head of this committee, was lord Liverpool, whofe talents for bufinefs have been long acknowledged.

In 1805, his lordfhip publifhed a "Treatife on the Coins of the Realm, in a Letter to the King," a work of great intelligence and refearch, and which contains a very accurate hiftory of the Britifh coins, from the conqueft to the prefent time; and alfo a learned and interefting difquifition on the monetary regulations of the ancients.

Among the new principles which this publication is intended to eftablifh, are the following on coinage:

That the coins, which are the principal meafure of property, fhould be compofed of one metal only.—That this metal fhould be gold.—And that the expences of fabrication (*i. e.* the mint expences) fhould be taken out of the filver and copper coins.

Thefe principles, as well as various other important queftions in lord Liverpool's work, are ably inveftigated by Mr. Wheatly in a recent publication, entitled "An Effay on the Theory of Money, and the Principles of Commerce." But as the plan of the new coinage is not yet finally fettled, or, at leaft, not made known to the public, we want data to proceed on the fubject. We fhall therefore clofe the prefent article with the following tables of the principal coins now in circulation; and when our work arrives at the articles MINT and MONEY, we propofe to give an account of whatever new coinages may have then taken place in England and elfewhere, and alfo to give full and accurate tables of all the real and imaginary monies of the Univerfe.

A TABLE

Zurich, -	Ecu, or rix-dollar -	436.90	10	7	376.83	2 florins	4	$4\frac{1}{2}$

In the foregoing tables, double pieces, and the fractional parts of coins are generally omitted, eſpecially where they are of the ſame ſtandard, and of the due proportional weight. Thus, double and half Louis-d'ors are omitted, as their weight and value may be found from the ſingle Louis-d'or. The ſame may be obſerved of the Souverain, the Frederick, the Eagle, the Italian and Spaniſh piſtoles; the Portugal and Italian gold coins, and the ſilver coins of moſt countries. In ſome places, however, the inferior pieces are of inferior ſtandard; and ſuch are noticed in the table.

It ſhould be alſo obſerved that the fineneſs of gold and ſilver, in the foregoing tables, is expreſſed in the Engliſh manner; although a difference prevails in this reſpect in moſt countries.

Some nations expreſs the fineneſs of gold, like the Engliſh, by ſuppoſing the whole weight to be divided into 24 equal parts, or carats; but the diviſions of the carat vary. In America, Turkey, Spain, and Portugal, the carat is divided, as in England, into 4 grains; in Holland, Germany, Sweden, and Denmark, it is divided into 12 grains; in Genoa and Leghorn, it is divided into 8; in Rome, Milan, and other parts of Italy, into 24 parts; and in the old ſyſtem of France the carat was divided into 32 parts; but in all the above places, the number of carats is 24.

The fineneſs of ſilver in Holland, Portugal, Spain, and moſt parts of Italy, is expreſſed by dividing the unit or pound into 12 parts, called deniers, denari, or penny-weights; in Genoa, the pound of fine ſilver is divided into 12 ounces, and the ounce into 24 denari; in Germany, Switzerland, Denmark, and Sweden, the mark is divided into 16 loths, and the loth into 18 grains. In Turkey they reckon, for ſilver, 100 carats, and each carat is 4 grains.

In ſome countries, the expreſſion of fineneſs, both of gold and ſilver, is the ſame. Thus, in France, according to the new ſyſtem, any quantity of either metal is ſuppoſed to be divided into 1000 equal parts, called millieme's. In Ruſſia, they reckon the pound of each metal at 96 ſolotnicks; in Venice, at 1152 carats. In China, and the Eaſt Indies, pure gold or ſilver is ſaid to be 100 touch, and the degrees of fineneſs are expreſſed by the 100th parts; thus 90 touch means 90 parts of pure metal, and 10 of alloy, that is $\frac{9}{10}$ths fine.

It may alſo be uſeful to know that the aſſayers of gold and ſilver in England, in their reports, do not expreſs the fineneſs (as it is in theſe tables) by the whole proportion of pure metal, and its alloy; but by the quantity in which it differs from the Engliſh ſtandard. Thus, a Dutch ducat is ſtated to be 1 carat, 2 grains, B. that is, better than Engliſh ſtandard, which means that it is 23 carats, 2 grains fine; and a French ſilver piece of 5 francs is ſtated to be 7 dwts. W. that is, worſe than Engliſh ſtandard.

As the value of the coins in the foregoing tables is only computed at the Engliſh mint price; it will be proper to ſhew how their value may be found at any other price. Suppoſe, for example, it is required to find the value of a Portugal Joaneſe at 4 *l.* per oz. The weight, per table, being 221.4 grs. and the fineneſs 22 carats.

Here the fineneſs being the ſame as the Engliſh ſtandard, the value of the price may be found by a ſingle ſtating: thus,

As 1 oz. or 480 grs. : 80 *s.* :: 221.4. grs. : 36 *s.* $10\frac{4}{5}$*d.* the value required.

But if it be required to find the value of a Spaniſh dollar, of the weight of 418.47 grs. and 10 oz. 15 dwts. fine, the market price of ſtandard ſilver being 5 *s.* 8 *d.* per oz.

Here

Here the finenefs muft be firft reduced to the Englifh ftandard; thus,

As 11 oz. 2 dwts. : 10 oz. 15 dwts. or as 222 : 215 :: 418.47 grs. : 405.275 grs.; the quantity of ftandard filver contained in the dollar.

Then, as 480 grs. : 405.275 grs. :: 68 *d.* : 4 *s.* $9\frac{1}{2}$ *d.* the value required; which agrees with the prefent market price of new dollars, that is, 5 *s.* 6 *d.* per oz. for as 405.275 grs. : 4 *s.* $9\frac{1}{2}$ *d.* :: 1 oz. : 5 *s.* 6 *d.*

Suppofe it were required to find the value in fterling of a French 5 franc piece, from the following report of the affayer, weight 16 dwts. 1 gr.—Finenefs 7 dwts. W. Here 11 oz. 2 dwts. — 7 dwts. = 10 oz. 15 dwts.; then fay,

As 11 oz. 2 dwts. : 10 oz. 15 dwts. or as 222 : 215 :: 385 grs. : 372.9 grs.; the quantity of ftandard filver contained in the piece.

Then as 1 oz. or 480 grs. : 372.9 grs. :: 62 *d.* : 48.17 *d.* or 4 *s.* $0\frac{1}{4}$ *d.* nearly, the value of the piece according to the mint price; but according to the prefent market price, 5 *s.* 8 *d.*, it is worth 4 *s.* $4\frac{3}{4}$ *d.*

The following are the principal writers on coins. Arbuthnot on ancient coins. Locke, Lowndes, Snelling, Folkes, and lord Liverpool on Englifh coins. Simon on Irifh coins. Le Blanc, and Bouteroue on French. Benaven on Italian. Bircherod on Danifh, and Brenner on Swedifh coins. The following authors have written on coins in general, Kraufe of Hamburgh. Ricard of Amfterdam. Gerhart of Berlin. Marien of Spain. Richbourg and Bonneville of France, and Du Boft of London. A general treatife on coins, including exchanges, weights, and meafures, is now in the prefs, and will fhortly be publifhed, under the title of the "Univerfal Cambift," from the manufcript of which the prefent article has been extracted.

Coin, *Laws relating to.* The coining of money is in all ftates the act of the fovereign power, that its value may be thus known on infpection: and with refpect to coinage in general, there are three fubjects of confideration, *viz.* the materials, the impreffion, and the denomination.

With regard to the materials, fir Edward Coke lays it down (2 Inft. 577), that the money of England muft be either of gold or filver; and none other was ever iffued by the royal authority till 1672, when copper farthings and half-pence were coined by king Charles II., and ordered by proclamation to be current in all payments under the value of fix-pence, and not otherwife. But this copper-coin is not upon the fame footing with the other in many refpects, particularly with regard to the offence of counterfeiting it. And, as to the filver coin, it is enacted by ftatute 14 Geo. III. c. 42, that no tender of payment in filver money, exceeding 25 pounds at one time, fhall be a fufficient tender in law, for more than its value by weight, at the rate of 5 *s.* 2 *d.* an ounce.

As to the impreffion, the ftamping of it is the unqueftionable prerogative of the crown; for, though divers bifhops and monafteries had formerly the privilege of coining money, yet, as fir Matthew Hale obferves (1 Hal. P. C. 191), this was ufually done by fpecial grant from the king, or by prefcription, which fuppofes one; and, therefore, was derived from, and not in derogation of, the royal prerogative. Befides that they had only the profit of the coinage, and not the power of inftituting either the impreffion or the denomination; but had ufually the ftamp fent them from the exchequer.

The denomination, or the value for which the coin is to pafs current, belongs likewife to the king's prerogative; and, if any unufual pieces are coined, that value muft be afcertained by proclamation. In order to fix the value, the weight and finenefs of the metal are to be jointly confidered. When a given weight of gold or filver is of a given finenefs, it is then of the true ftandard, and called eafterling, or fterling metal. (See Coin *fupra.*) And of this fterling metal, all the coin of the kingdom muft be made, by ftat. 25 Edw. III. c. 13. So that the king's prerogative, as judge Blackftone obferves, feemeth not to extend to the debafing or inhancing the value of the coin, below or above the fterling value (2 Inft. 577.); though fir Matthew Hale (1 Hal. P. C. 194.) appears to be of another opinion. The king may alfo, by his proclamation, legitimate foreign coin, and make it current here; declaring at what value it fhall be taken in payments. (Ibid. 197.) But this, Blackftone apprehends, ought to be by comparifon with the ftandard of our own coin; otherwife the confent of parliament will be neceffary. There is at prefent no fuch legitimated money; Portugal coin being only current by private confent, fo that every one who pleafes may refufe to take it in payment. The king may alfo at any time decry, or cry down, any coin of the kingdom, and make it no longer current. (1 Hal. P. C. 197.)

Two offences refpecting the coin are made treafon by the ftatute 25 Edw. III. c. 2. Thefe are the actual counterfeiting of the gold and filver coin of this kingdom, or the importing of fuch counterfeit money with an intent to utter it, knowing it to be falfe. The crime itfelf is made a fpecies of high treafon; as being a breach of allegiance by infringing the king's prerogative, and affuming one of the attributes of the fovereign, to whom alone it belongs to fet the value and denomination of coin made at home, or to fix the currency of foreign money; and, befides, as all money, which bears the ftamp of the kingdom, is fent into the world upon the public faith, as containing metal of a particular weight and ftandard, whoever falfifies this is an offender againft the ftate, by contributing to render that public faith fufpected. Upon the fame reafons, by a law of the emperor Conftantine (C. 29. 24. 2. Cod. Theod. de falfa Moneta, l. 9.), falfe coiners were declared guilty of high treafon, and were condemned to be burnt alive; as, by the laws of Athens (Potter, Antiq. B. i. c. 26.), all counterfeiters, debafers, and diminifhers of the current coin were fubjected to capital punifhment. This method of reafoning, however, fays judge Blackftone, is a little overftrained; counterfeiting or debafing the coin being ufually practifed, rather for the fake of private and unlawful lucre, than out of any difaffection to the fovereign. And therefore, both this and its kindred fpecies of treafon, that of counterfeiting the feals of the crown, or other royal fignatures, feem better denominated by the later civilians a branch of the "crimen falfi," or forgery, (in which they are followed by Glanvil (l. 14. c. 7.), Bracton (l. iii c. 3. § 1 and 2.), and Fleta (l. 1. c. 22.), than by Conftantine and our Edward III. a fpecies of the "crimen læfæ majeftatis," or high treafon. For this confounds the diftinction and proportion of offences; and, by affixing the fame ideas of guilt upon the man who coins a leaden groat, and him who affaffinates his fovereign, takes off from that horror which ought to attend the very mention of the crime of high treafon, and makes it more familiar to the fubject. Before the ftatute 25 Edw. III., the offence of counterfeiting the coin was held to be only a fpecies of petit treafon (1 Hal. P. C. 224.); but fubfequent acts in their new extenfions of the offence have followed the example of that ftatute, and have made it equally high treafon with an endeavour to fubvert the government, though not quite equal in its punifhment. In confequence of the principle thus adopted, the ftatute 1 Mar. c. 1, having at one ftroke repealed all intermediate treafons created fince the 25 Edw. III., it was

 thought

thought expedient by ſtat. 1 Mar. ſt. 2. c. 6. to revive two ſpecies thereof, *viz.* 1. That if any perſon falſely forge or counterfeit any ſuch kind of coin of gold or ſilver, as is not the proper coin of this realm, but ſhall be current within this realm by conſent of the crown; or, 2. Shall falſely forge or counterfeit the ſign manual, privy ſignet, or privy ſeal; ſuch offences ſhall be deemed high treaſon. And by ſtatute 1 and 2 P. and M. c. 11., if any perſons do bring into this realm ſuch falſe or counterfeit foreign money, being current here, knowing the ſame to be falſe, with intent to utter the ſame in payment, they ſhall be deemed offenders in high treaſon. The money referred to in theſe ſtatutes muſt be ſuch as is abſolutely current here, in all payments, by the king's proclamation; of which there is none at preſent, Portugal money being only taken by conſent, as approaching the neareſt to our ſtandard, and falling in well enough with our diviſions of money into pounds and ſhillings; therefore, to counterfeit it is not high treaſon, but another inferior offence.

Clipping or defacing the genuine coin was not hitherto included in theſe ſtatutes; though an offence equally pernicious to trade, and an equal inſult upon the prerogative, as well as perſonal affront to the ſovereign; whoſe very image ought to be had in reverence by all loyal ſubjects. And, therefore, among the Romans, (Ff. 48. 4. 6.), defacing or even melting down the emperor's ſtatues was made treaſon by the Julian law; together with other offences of the like ſort, according to that vague concluſion, "aliudve quid ſimile ſi admiſerint." And now, in England, by ſtatute 5 Eliz. c. 11, clipping, waſhing, rounding, or filing, for wicked gain's ſake, any of the money of this realm, or other money ſuffered to be current here, ſhall be adjudged high treaſon; and by ſtatute 18 Eliz. c. 1, the ſame ſpecies of offence is deſcribed in other more general words, *viz.* impairing, diminiſhing, falſifying, ſcaling, and lightening, and made liable to the ſame penalties. By ſtat. 8 and 9 W. III. c. 26, made perpetual by 7 Ann. c. 25, whoever, without proper authority, ſhall knowingly make or mend, or aſſiſt in ſo doing, or ſhall buy, ſell, conceal, hide, or knowingly have in his poſſeſſion, any implements of coinage ſpecified in the act, or other tools or inſtruments proper only for the coinage of money; or ſhall convey the ſame out of the king's mint; he, together with his counſellors, procurers, aiders, and abettors, ſhall be guilty of high treaſon. The ſtatute proceeds to enact, that to mark any coin on the edges with letters, or otherwiſe, in imitation of thoſe uſed in the mint; or to colour, gild, or caſe over any coin reſembling the current coin, and even round blanks of baſe metal, ſhall be conſtrued high treaſon. But all proſecutions on this act are to be commenced within *three* months after the commiſſion of the offence; except thoſe for making or mending any coining tool or inſtrument, or for marking money round the edges; which are directed to be commenced within *ſix* months after the offence committed. (Stat. 7 Ann. c. 25.) And, laſtly, by ſtatute 15 and 16 Geo. II. c. 28, if any perſon colours or alters any ſhilling or ſix-pence, either lawful or counterfeit, to make them reſpectively reſemble a guinea or half-guinea; or any half-penny or farthing to make them reſpectively reſemble a ſhilling or ſix-pence; this is alſo high treaſon; but the offender ſhall be pardoned in caſe (being out of priſon) he diſcovers and convicts two other offenders of the ſame kind. For the puniſhment of this ſpecies of treaſon; ſee TREASON.

Offences relating to the coin, not amounting to treaſon, to which claſs we may refer ſome inferior miſdemeanors that do not amount to felony, are thus declared by a ſeries of ſtatutes, which we ſhall recite in the order of time. By ſtat. 27 Edw. I. c. 3. none ſhall bring pollards and crockards, which were foreign coins of baſe metal, into the realm, on pain of forfeiture of life and goods. But by ſtat. 9 Edw. III. ſt. 2. no ſterling money ſhall be melted down, upon pain of forfeiture thereof. By ſtat. 17 Edw. III. none ſhall be ſo hardy as to bring falſe and ill money into the realm, on pain of forfeiture of life and member by the perſons importing, and the ſearcher permitting ſuch importation. By ſtat. 3 Hen. V. ſt. 1. to make, coin, buy, or bring into the realm, any gally-halfpence, ſuſkins, or dotkins, in order to utter them, is felony; and knowingly to receive or pay either them or blanks, (ſt. 2 Hen. VI. c. 9.) is forfeiture of 100*s*. By ſtat. 14 Eliz. c. 3. ſuch as forge any foreign coin, although it be not made current here by proclamation, ſhall (with their aiders and abettors) be guilty of miſpriſion of treaſon. By ſtat. 13 and 14 Car. II. c. 31. the offence of melting down any current ſilver money ſhall be puniſhed with forfeiture of the ſame, and alſo the double value; and the offender, if a freeman of any town, ſhall be disfranchiſed; if not, ſhall ſuffer ſix months' impriſonment. By ſtat. 6 and 7 Will. III. c. 17. if any perſon buys or ſells, or knowingly has in his cuſtody, any clippings or filings of the coin, he ſhall forfeit the ſame, and 500*l.*; one moiety to the king, and the other to the informer; and be branded in the cheek with the letter R. (See *Benefit of* CLERGY.) By ſtat. 8 and 9 Will. III. c. 26. if any perſon ſhall blanch or whiten copper for ſale, (which makes it reſemble ſilver), or buy or ſell, or offer for ſale, any malleable compoſition, which ſhall be heavier than ſilver, and look, touch, and wear like gold, but be beneath the ſtandard; or if any perſon ſhall receive or pay at a leſs rate than it imports to be of, (which demonſtrates a conſciouſneſs of its baſeneſs, and a fraudulent deſign), any counterfeit or diminiſhed milled money of this kingdom, not being cut in pieces, an operation which is expreſsly directed to be performed when any ſuch money ſhall be produced in evidence, and which any perſon, to whom any gold or ſilver money is tendered, is empowered, by ſtats. 9 and 10 Will. III. c. 21. 13 Geo. III. c. 71. and 14 Geo. III. c. 70. to perform at his own hazard, and the officers of the exchequer, and receivers-general of the taxes, are particularly required to perform; all ſuch perſons ſhall be guilty of felony, and may be proſecuted for the ſame at any time within three months after the offence committed.

But theſe precautions not being found ſufficient to prevent the uttering of falſe or diminiſhed money, which was only a miſdemeanor at common law, it is enacted by ſtatute 15 and 16 Geo. II. c. 28. that if any perſon ſhall utter or tender in payment, any counterfeit coin, (give in exchange, pay, or put off, 37 Geo. III. c. 126.) knowing it ſo to be, he ſhall, for the firſt offence, be impriſoned ſix months, and find ſecurity for his good behaviour for ſix months more; for the ſecond offence, ſhall be impriſoned two years, and find ſureties for two years longer; and, for the third offence, ſhall be guilty of felony without benefit of clergy. By the ſame ſtatute it is alſo enacted, that if any perſon counterfeits the copper coin, he ſhall ſuffer two years impriſonment, and find ſureties for two years more. By ſtat. 11 Geo. III. c. 40, perſons counterfeiting copper half-pence or farthings, with their abettors, or buying, ſelling, receiving, or putting off any counterfeit copper money (not being cut in pieces, or melted down) at a leſs value than it imports to be of, ſhall be guilty of a ſingle felony. This ſtatute alſo enacts, that one juſtice, on complaint upon oath that there is juſt cauſe for ſuſpicion againſt any perſons being concerned in counterfeiting the copper monies of this realm, may, by his warrant, cauſe the dwelling-houſe, &c. of ſuch ſuſpected perſon

ſon

ſon to be ſearched for coining tools and inſtruments; and if they be found, they ſhall be ſeized and produced in evidence againſt the proſecuted perſon, and afterwards defaced or deſtroyed, or diſpoſed of at the pleaſure of the court or juſtice. By 14 Geo. III. c. 42. which act was at firſt temporary, and was ſuffered to expire, but revived and made perpetual by 39 Geo. III. c. 75. if any quantity of money, exceeding the ſum of five pounds, being or purporting to be the ſilver coin of this realm, but below the ſtandard of the mint in weight or fineneſs, ſhall be imported into Great Britain or Ireland, the ſame ſhall be forfeited, and proſecuted in any court of record at Weſtminſter; but if it do not amount in value to 20*l.*, the ſame may be proſecuted in a ſummary way before two juſtices, at the election of the commiſſioners of the cuſtoms; and after condemnation, melted down or otherwiſe defaced, and ſhall be divided in equal moieties to the crown and proſecutor. By 37 Geo. III. c. 126. ſo much of the above-mentioned acts of 15 Geo. II. c. 28. and 11 Geo. III. c. 40. and all other acts concerning the copper monies, called an half-penny and a farthing, or any other copper money of this realm, ſhall extend to all copper money which ſhall be coined and iſſued by order of his majeſty. By the ſame ſtatute, if any perſon ſhall make, coin, or counterfeit any coin, not the proper coin of this realm, nor permitted to be current in it, but reſembling, or made with intent to reſemble any gold or ſilver coins of any foreign ſtate, or to paſs as ſuch, or if any perſon ſhall bring into this realm any falſe or counterfeit foreign coin, knowing the ſame to be ſo, with the intent of uttering the ſame within this realm; he ſhall, in either caſe, be guilty of felony, and may be tranſported for a term not exceeding ſeven years. By the ſame ſtatute, if any perſon ſhall have in his cuſtody, without lawful excuſe, more than five pieces of any falſe or counterfeit foreign coin, or made with intent to reſemble or paſs as ſuch foreign coin, he ſhall, upon conviction, on the oath of one witneſs, before one juſtice, forfeit the ſame, which ſhall be cut in pieces and deſtroyed by order of ſuch juſtice, and ſhall alſo forfeit not exceeding 5*l.* nor leſs than 40*s.* for every piece found in his cuſtody; half to the informer, and half to the poor; and if not forthwith paid, ſuch offender may be committed to the gaol, or houſe of correction to hard labour, for three calendar months, or till ſuch penalty ſhall be paid. By 43 Geo. III. c. 139. the counterfeiting of foreign coin is a miſdemeanor and breach of the peace; and the perſon that is convicted, ſhall, for the firſt offence, be impriſoned not exceeding a year, and for the ſecond offence be tranſported for ſeven years. The ſame ſtatute enacts penalties on perſons having more than five pieces of ſuch coin in their poſſeſſion, and directs the houſes of ſuſpected perſons to be ſearched, and counterfeit coin ſeized, &c. &c. By the ſame ſtatute, amending ſo much of ſeveral acts of 6 and 7, 7 and 8 Will. as relates to the exportation of ſilver bullion, the treaſury may grant licences for the exportation of molten ſilver and bullion; and perſons ſo licenſed may export ſuch bullion without the uſual certificates. But if any bullion is entered to be exported, otherwiſe than in the name of the true owner or importer, the exporter ſhall forfeit the ſame, or value, half to the king, and half to him who ſhall ſeize or diſcover the ſame.

By 3 Edw. I. c. 15. perſons taken for falſe money are not bailable by juſtices of the peace. It is not neceſſary there ſhould be two witneſſes in caſes of counterfeiting the coin, as it is in other high treaſons; but perſons may be convicted according to the courſe of the common law, by one witneſs only. The reward for apprehending and convicting an offender againſt the ſtatutes relating to gold and ſilver coin, is 40*l.* in order to obtain which, the judge ſhall give a certificate of the conviction, and the ſheriff, on its being tendered, ſhall pay the ſame without fee, within one month after tender and demand, on pain of forfeiting to the party, double the ſum with treble coſts: and the ſheriff ſhall be repaid out of the treaſury, 6 and 7 W. c. 17. 15 Geo. II. c. 28. In like manner, a reward of 10*l.* ſhall be paid for apprehending and convicting one who counterfeits the copper money. 15 Geo. II. c. 28. The commiſſioners of the treaſury may iſſue a ſum not exceeding 600*l.* yearly, for the charge and expences of the officers, and others employed in the proſecution of offences of this kind. 7 Ann. c. 24. 15 Geo. II. c. 28.

In Scotland, by the articles of the Union, it is appointed, that all the coins be reduced to the Engliſh, and the ſame accompts obſerved throughout. Till that period the Scots had their pounds, ſhillings, and pence, as in England; but their pound was twenty pence Engliſh, and the others were in proportion: accordingly, their mark was $13\frac{1}{3}$*s.* Scots, current in England at $13\frac{1}{2}$*d.* their noble in proportion. Beſides theſe, they had their Turnorer pence, and half-pence; their penny, one twelfth of that of England; beſides baſe money of achiſons, baubees, and placks: the boddle, one ſixth of the penny, one fourth of the achiſon, one third of the baubee, and one half of the plack.

In Ireland, the coins are as in England; viz. ſhillings, pence, &c. with this difference, that their ſhilling or harper, is but equal to $11\frac{3}{10}$*d.* ſterling; or a ſhilling Engliſh is equal to twenty-ſix half-pence: whence their pound is only 18*s.* $4\frac{1}{2}$*d.* of Engliſh money. For an account of the coins of different parts of the world, with their proportions or values, we refer to the article MONEY. See alſo COIN *Supra*.

COINS, *Shells current for*.—Theſe ſerve in many places for money; and are brought from the Maldives, and called in the Indies *cowries*: on the coaſts of Africa, they change their names, and are called *bouges*.

In America they take a third name, *viz. porcelains*. Indeed thoſe laſt do come from the Maldives; there being ſhells found in the Weſt Indies much like thoſe of the Eaſt.

In the knigdom of Congo there is another kind of ſhells, called *zimbi*; though ſome will have them the ſame with the cowries. Cowries, coris, or bouges, are white ſhells, current particularly in the ſtates of the Great Mogul: ſixty-five are uſually reckoned equivalent to the done, a ſmall copper coin, worth about a halfpenny ſterling; which brings each cowry to $\frac{1}{130}$th of a penny ſterling.

Porcelains are nearly on the ſame footing with the cowries. See PORCELAIN.

Zimbi are current, particularly in the kingdoms of Angola and Congo. Two thouſand zimbis make what the negroes call a *maciute*, or *macoute*; which is no real money, whereof there is none in this part of Africa, but only a manner of reckoning: thus, two Flemiſh knives they eſteem a macoute; a copper baſon, two pounds weight, and twelve inches diameter, three macoutes; a fuſee ten, &c.

COINS, *Fruits current for*.—There are kinds of fruits current for coins; two in America, particularly among the Mexicans, which are the cacao and maiſe: the other in the Eaſt Indies, *viz.* almonds, brought thither from Lar, and growing in the deſarts of Arabia.

Cacao, fifteen of theſe are eſteemed equivalent to a Spaniſh rial, or ſeven-pence ſterling. See CACAO.

Maiſe has ceaſed to be a common money ſince the diſcovery of America by the Europeans.

Almonds are chiefly uſed where the cauris are not current. As the year proves more or leſs favourable to this fruit, the

value

value of the money is higher or lower: in a common year, forty almonds are set againſt a percha, or halfpenny ſterling; which brings each almond to $\frac{1}{20}$th of a farthing.

Coins, *Ancient*, are thoſe chiefly which have been current among the Greeks, Jews, and Romans.

For Jewiſh Coins, *their Values and Proportions ſtand thus:*

				(Sterling.)	*l.*	*s.*	*d.*
				Gerah	0	0	$1\frac{50}{160}$

40	20	10	4	2	Denarius,	0	7	3

Note: Of theſe the denarius, victoriatus, ſeſtertius, and ſometimes the as, were of ſilver, the reſt of braſs.

There were ſometimes alſo coined of braſs the triens, ſextans, uncia, ſextula, and dupondius.

(Sterling.)	*l.*	*s.*	*d.*
The Roman gold coin was the aureus, which weighed generally double the denarius; the value of which, according to the firſt proportion of coinage, mentioned by Pliny, was,	1	4	$3\frac{3}{4}$
According to the proportion that obtains now amongſt us, worth,	1	0	9
According to the decuple proportion mentioned by Livy and Julius Pollux, worth,	0	12	11
According to the proportion mentioned by Tacitus, and which afterwards obtained, whereby the aureus exchanged for 25 denarii, its value,	0	16	$1\frac{3}{4}$

Theſe tables are formed on the ſuppoſition that ſilver is worth five ſhillings, and gold four pounds an ounce. See Arbuthnot's Tables of Ancient Coins. See alſo on this ſubject an excellent paper by M. Raper, eſq. intitled "An Enquiry into the Value of the Ancient Greek and Roman Money, in the Phil. Tranſ. vol. lxi. part ii. art. 48. p. 462. See Denarius and Drachm. For a more particular and ample account of ancient coins and coinage; ſee the article Medal. See alſo Money.

Coin, in *Architecture*, a kind of dye, cut diagonal-wiſe, after the manner of the flight of a ſtair-caſe; ſerving at bottom to ſupport columns in a level; and at top to correct the inclination of an entablature, ſupporting a vault.

Theſe coins have alſo the ſame effect with round baluſters, which are not inclined according to any flight.

Coin *d'Artilleur.* Coins in gunnery are wedges which artilleriſts lay under the breeches of guns, for the purpoſe of raiſing or depreſſing and pointing them. They are commonly notched at the ſides, that they may the more eaſily be puſhed forward or drawn back.

Coin *de Manœuvre Militaire*, a certain diſpoſition or arrangement of troops, which the ancients made uſe of for penetrating into and breaking an enemy's line. It conſiſted of a corps, or body of troops, formed with a conſiderable depth, and very ſmall extent of front.

Coin is alſo uſed for a ſolid angle, compoſed of two ſurfaces

faces inclined towards each other; whether that angle be exterior, as the coin of a wall, a tree, &c. or interior, as the coin of a chamber, or chimney: from the word *cuneus*, wedge. See Quoin.

Coins, on board a man of war. See Quoins.

Coin-*moulds*. See Moulds.

Coins, *Canting*, on board a ſhip, little ſhort pieces of wood, or billets, cut wedge-like, to lie betwixt the caſks.

Coins, *Standing*, on board a ſhip, billets, or pipe-ſtaves, to keep the caſks from ſtirring, or giving way.

Standing-coins are made of barrel boards, about four inches broad, and of a fit length to be driven in between the ends of a caſk, about two or three hoops from the chine hoops, to keep the butts from jogging.

COINAGE, or Coining, or the art of making money, has hitherto been chiefly performed either by the hammer or the mill. The firſt method is now, and has, indeed, been long generally diſuſed, though it was the only one known till the reign of Henry II. of France, when the coining-mill was invented by Antoine Brucher, a French engraver, and the firſt money was ſtruck with it in that kingdom in the year 1553. The uſe of it continued there till 1585, when, in the 12th year of Henry III. it was laid aſide, on account of its great expence in compariſon of the coinage with the hammer; nor was it revived till the year 1645, when, by an edict of Louis XIV., it was eſtabliſhed for perpetuity. Queen Elizabeth had milled money, ſtruck in England ſo early as the year 1562; but it did not continue for more than 10 years; and the hammer was again adopted as leſs expenſive. This example was ſoon followed in France, till the ſubſequent ſucceſs of the mill in England was probably the cauſe of its re-eſtabliſhment in that kingdom, in 1645. Briot, a French artiſt, failing to induce the government of France to adopt the uſe of the mill, came to England in 1623.

Thus, this machine, like moſt new inventions, met at firſt with various fate, it being ſometimes uſed, and at others laid aſide; but in the 14th year of Charles II., that is, in the year 1662, the uſe of the mill and ſcrew (hereafter to be deſcribed) was finally eſtabliſhed in the mint of this kingdom.

Soon after the revival of the mill in this kingdom by Briot, the coinage of England arrived at a degree of perfection to which it had never before attained. This was owing in a great degree to the ingenuity of Thomas Simon, ſuppoſed to be a native of Yorkſhire, who, upon the return of Briot to France in 1646, ſucceeded him as chief engraver at the mint.

It was at this period, alſo, that graining was firſt placed on the edges of all our coins, and ſuch confidence was then placed in this new device, that it was deemed impoſſible for the coins of this kingdom to be injured by clipping or wearing. Experience, however, in a very ſhort time, proved that milled money, either of gold or ſilver, could be diminiſhed with great facility and expedition. This fraudulent practice was well known and carried on in the reign of king William.

In coining, either by the hammer or mill, the pieces of metal are ſtamped, or ſtruck, with puncheons or dyes, in which are engraved the ſovereign's effigies, with arms, legend, &c.

The ancients uſed neither the puncheon nor the matrice, but merely cut the impreſſion upon a ſteel dye; both are now uſed. The puncheon is a high-tempered piece of ſteel, upon which the coin is engraven in relievo, and then ſtamped upon the matrice, which is a piece of ſteel four or five inches long, ſquare at the bottom, and round at the top. The moulding of the border, and letters, are added on the matrice, with ſmall, ſharp, ſteel puncheons. When thus completed, it is called a dye. The puncheon thus ſaves much labour in repeatedly engraving the ſubject of the coin; for a dye will ſometimes break with ſtriking one coin, the neceſſary force being ſo great.

It is not certain when this improvement commenced. It is believed that Simon, already mentioned, firſt introduced the idea of marking the crown and half-crown with a legend on the edge, as an ornament and protection to the coin; but the original inventor of this art is unknown. The firſt piece, yet known as an inſtance of it, is a ſilver "piedfort" of Charles IX. of France, dated 1573. The firſt medal is one in ſilver, of George Frederic, marquis of Brandenburg, dated 1589. Briot gave the firſt ſpecimen of it in Great Britain upon his Scottiſh coronation medal in 1633; and Simon, as we have juſt mentioned, introduced it into the larger coin, with great propriety, as it is both ornamental and preſerves ſuch pieces from being clipped. This operation is performed, ſince the year 1685, by means of a very ſimple, but ingenious machine, invented by M. Caſtaing, and then introduced into the French mint; and ſince that time into all the mints of Europe. It is deſcribed in the ſequel of this article.

The firſt operations are, the mixing and melting of the metal, becauſe there is no ſpecies of coin of pure gold or ſilver, but always a quantity of alloy of copper is mixed with them, or for the gold coin, the alloy is a mixture of ſilver and copper, as ſilver alone would make the coin too pale, and copper would give too high a colour. The alloy is uſed to render the coins harder, and leſs liable to be diminiſhed by art. See Alloy and Coin.

When the gold and ſilver are completely melted and mixed, they are poured into moulds, or frames, for caſting them into long flat bars: the method of doing this is preciſely the ſame with that uſed by founders, in ſand; both with regard to the frame, the manner of working the earth, and that of ranging the models, or patterns. Theſe patterns are flat plates of copper, about fifteen inches long, and nearly of the thickneſs of the ſpecies to be ſtruck. The only difference between caſting the bars of gold, and thoſe of other metals, conſiſts in this: that the latter are taken out of the crucibles with ladles, and poured into the aperture of the mould; and that for gold, the crucible is taken off from the fire with a pair of tongs, made for the purpoſe, and the metal is thence poured into the mould.

In coining by the mill, or milled money, the bars are taken out of the moulds, and ſcraped and bruſhed; they are then flattened in a mill, and brought to the proper thickneſs of the ſpecies to be coined. There is, however, this difference, that the plates of gold are heated again in a furnace, and quenched in water, before they undergo the operation of the mill; but the plates of ſilver are paſſed through the mill without any additional heating. The plates, whether of gold, ſilver, or copper, thus reduced as nearly as poſſible to their proper thickneſs, are cut into round pieces, called blanks, or planchets, with an inſtrument faſtened to the lower extremity of an arbor, whoſe upper end is formed into a ſcrew, which being turned by an iron handle, turns the arbor, and lets the ſteel, well ſharpened, in form of a punch cutter, fall on the plates; and thus a piece is punched out. See *Plate* (*Coinage*) *fig.* 1.

The pieces are now to be brought to the ſtandard weight by filing or raſping, and what remains of the plate between the circles is melted again, under the denomination of ſizel.

The

The pieces are now weighed in a very accurate balance, and thofe that prove too light are remelted, but thofe that are too heavy are filed to the ftandard weight. When the blanks are adjufted, they are carried to the blanching-houfe, that is, the place where the gold blanks are brought to their proper colour, and the filver ones are whitened; which operation is performed by heating them in a furnace, and when cooled, boiling them fucceffively in two copper veffels, with water, common falt, and tartar, and after that fcouring them well with fand, and wafhing them with clear water, drying them over a wood fire, in a copper fieve, in which they are put when taken out of the boiler. Formerly the planchets, as foon as blanched, were carried to the prefs to be ftruck, and receive their impreffions; but now they are firft milled. The machine ufed for this purpofe confifts of two plates of fteel in form of rulers, on which the edging is engraved, half on the one, and half on the other. One of thefe plates is immoveable, being ftrongly bound with fcrews to a copper plate on a board or table; the other is moveable, and flides on the copper plate by means of a handle, and a wheel, or pinion, of iron, the teeth of which catch in other teeth, on the furface of the fliding plate. The planchet, being placed horizontally between thefe two plates, is carried along by the motion of the moveable one; fo as by the time that it has made half a turn, it is found marked all round. See *fig.* 2. Laftly, the planchets, being thus edged, are to be ftamped: that is, the impreffion is to be given them in the mill, (fee *fig.* 3,) by the French denominated *balancier*. The chief parts of this machine are, a beam, fcrew, arbor, &c. all contained within the body of it, except the firft, which is a long iron bar, with a heavy ball of lead at each end, and rings, to which are faftened cords to give it motion. This bar is placed horizontally over the body of the machine; in the middle of the beam is faftened a fcrew, which, by turning the beam, ferves to prefs the arbor underneath it; to the lower extremity of the arbor, placed perpendicularly, is faftened the dye or matrix, of the reverfe or arm fide, in a kind of box, or cafe, in which it is retained by fcrews: and under this is a box containing the dye of the image fide, firmly fixed to the lower part of the engine. See *fig.* 4. When the planchet is to be ftamped, it is laid on the image-matrix, upon which two men draw one of the ropes of the beam, and turn the fcrew faftened in it; which, by this motion, lowers the arbor to which the dye of the arms is faftened: thus the metal, being in the middle, at once receives an impreffion on each fide, and becomes money, but they have not currency till they have been weighed and examined. For the coining of medals, the procefs is nearly the fame with that of money. The principal difference confifts in this: that money, having but a fmall relievo, receives its impreffion at a fingle ftroke of the engine; whereas for medals, the height of their relievo makes feveral ftrokes neceffary. For this purpofe, the piece is taken out from between the dyes, heated, and returned again; which procefs, in medallions, is fometimes repeated as many as fifteen or twenty times, before the full impreffion is given. Medallions, and medals of high relievo, are ufually firft caft in fand, and then put in the prefs to perfect them. Medals, therefore, receive their form and impreffion by degrees; money all at once.

In coining with the hammer, the bars of metal being taken out of the moulds, are heated and ftretched on an anvil; they are then cut to pieces, farther ftretched, and rounded with fheers; thus, by cutting and rounding they are reduced to the ftandard weight, and to the fize of the fpecies to be coined. The blanks, or planchets, thus formed, are carried to the blanching-houfe, where they undergo the fame preparation as the milled money defcribed above, and are fent to the minter to be ftamped with the hammer. For this laft operation, two puncheons, or matrices, are ufed: the one called the *pile*, and the other the *trufs*, or *quiver*; each engraven dent-wife; the pile bearing the arms, and the trufs the image; both their legend, date, &c. The pile, which is about eight inches high, has a kind of talon or heel in the middle, and ends in a point; this kind of figure was given, for the fake of being more eafily funk, and more firmly faftened to the block on which the money is ftruck. The minter, then, laying the planchet horizontally on the pile, and covering it with the trufs, which he holds fteadily in his left hand, gives feveral fmart blows on the trufs with an iron mallet held in the right; more or lefs, as the graving of the dyes is more or lefs deep. Thus the coinage is finifhed, and the blanks converted into money, which, after they have been examined, become current.

We have now given a brief account of the modes of coining hitherto adopted in this country.

About 16 or 17 years ago the ingenious Meffrs. Boulton and Watt of Birmingham began to apply the power of their fteam-engine at the Soho manufactory, to the operations of coining, and have fince coined a large quantity of two-penny, and penny pieces, of copper, and half-pence and farthings, for government, which are in general circulation; a few years ago, alfo, on the appearance of fcarcity in the circulating medium, thefe gentlemen re-coined a large quantity of Spanifh dollars for the Bank of England, without their being firft melted, or the Spanifh impreffion obliterated, by rolling, or otherwife. The Danifh government being defirous of introducing the approved coining apparatus of Boulton and Watt, at the royal mint at Copenhagen, fent over Olaus Warberg, one of the profeffors in the univerfity of that city, to contract for, and fuperintend the making of, and to learn the ufe of a complete fet of fteam-wrought coining apparatus; under the authority of a fpecial act of parliament for that purpofe, Meffrs. Boulton and Watt have almoft completed the apparatus for the Danifh mint; and ere long it is expected to be fhipped off for its deftination. A plan has been adopted by the Britifh government, for removing the royal mint out of the confined and inconvenient apartments in the Tower, where it has for fuch a length of time been carrried on, to an entire new edifice erected for the purpofe, on the fcite of what was formerly the victualling office, and fince the tobacco warehoufes, on the eaft fide of Tower-hill. The erections for the engines and apparatus, to be conftructed by Boulton and Watt, on their moft improved plan, have been begun upon a large fcale, and the whole will, when finifhed, prefent a fpectacle worthy of the nation. A great fecret has hitherto been made of the operations in the Soho mint, the motives for which we profefs not fully to underftand; it cannot, we think, arife, as fome have imagined, from the idea of preventing the clandeftine counterfeiting of the coin of the kingdom; becaufe, large and expenfive engines and apparatus like thefe, are not likely to be erected or ufed in a private manner; and, granting the poffibility of counterfeitors accomplifhing this, under cover of fome other mechanic art or trade, then we conceive, that men of fufficient fkill and ingenuity to carry fuch a work into effect, would not long be at a lofs to find out the principles of action adopted at Soho, from a ftudy of the impreffions on the coin in circulation. To us, it appears, from fuch an examination, that the impreffion is not given by a blow, or by the accelerated motion of a fcrew, as in the common methods, but by the fimple and powerful action of a crank, worked by the fteam-engine, and that the milling on the edge is done by the threads of an endlefs revolving fcrew, againft which the coin rolls; the rolling, or flatting and punching (or perhaps rolling) out the round pieces or blanks for coining, is probably effected by methods well known in other branches of the metallic arts.

This machinery works the fcrew-preffes for cutting out the circular pieces of copper, and coins both the faces and edges of the money at the fame time, with fuch fuperior excellence and cheapnefs of workmanfhip, as well as with marks of fuch powerful machinery, as muft totally prevent clandeftine imitation. By this machinery, four boys are capable of ftriking 30,000 pieces of money in an hour; and the machine acts at the fame time as a regifter, and keeps an unerring account of the number of pieces ftruck.

By the time that our work has advanced to the word Mint, we hope to be allowed to give an account of the new national mint, which will then probably be in action, or to obtain fufficient information thereof, for the gratification of our curious readers.

To this grand invention, the earl of Liverpool refers in his letter to the king, with furprife that it has not been already introduced into the practice of coining in this country: "But the new machinery," fays his lordfhip, "now employed in the manufactory of every fort of metal, in which the mechanics of this country far furpafs thofe of any other, has not in general been admitted into your majefty's mint. It is an acknowledged principle, that machines that act with a given force, can work with more truth and accuracy than the arm of man, the force of which neceffarily varies occafionally, from feveral caufes; another practice has been invented, that of ftriking coins in a fteel collar, fo as to make them perfectly round, and all precifely of the fame diameter, an improvement which certainly contributes to the beauty of the coin; new modes of putting what is called the grainery on the edges of the coins, have alfo been invented, which, at the fame time that they protect the coins from being filed, equally with the prefent mode, do not occafion thofe rough edges which expofe them to wear by abrafion or friction. For thefe, and many other valuable improvements, the public are indebted to the ingenuity of Mr. Boulton of Soho, near Birmingham. It is fingular, that though the manufacturers of England have greatly profited by thefe inventions, the officers of your majefty's mint have never, or not fufficiently, availed themfelves of them; the mints in foreign countries are in fearch of them, and their governments, in more than one inftance, have employed Mr. Boulton in erecting mints on his new principle; and parliament has authorifed the fame." Earl of Liverpool's "Treatife on the Coins of the Realm." Martin Folkes, efq. "On Englifh Coins." Darwin's "Bot. Garden."

The coinage of England is now performed wholly in the Tower of London; where there is a corporation for it, under the title of the *mint*.

Formerly there were here, as there are ftill in other countries, what we call the *rights of feignorage and braffage;* but fince the eighteenth year of king Charles II. there is nothing taken, either for the king, or for the expences of coining; it having been fettled by act of parliament, that all money fhould be ftruck at the public expence; fo that weight is returned for weight, to all perfons who carry their gold and filver to the Tower. See Coin.

There is a duty of ten fhillings per ton on wine, beer, and brandy imported, called the coinage duty, granted for defraying the expence of the king's coinage, but not to exceed 3000*l.* per annum, by ftat. 18. Car. II. cap. 5. and continued and advanced by fubfequent ftatutes, 4 and 5 Anne, cap. 22 1 Geo. I. cap. 43. 4 Geo. II. cap. 12 1 Geo. III. cap. 16, &c. By ftatute 27 Geo. II. c. 11. (explained by ftat. 27. Geo. III. c. 13. f. 64.) the treafury is to apply 15,000 *l.* a year to the expences of the mints in England and Scotland. The ftatute 14 Geo. III. c. 92. regulates the ftamping of money-weights, the fees for which are fettled by ftat. 15 Geo. III. c. 30. at 1 *d.* for every 12 weights.

The fpecies coined in England are efteemed contraband goods, and not to be exported; all foreign fpecies are allowed by act of parliament, made in 1673, to be fent out of the realm; as well as gold and filver in bars, ingots, duft, &c.

Coinage *of Fez and Tunis* is not under any difcipline; each goldfmith, Jew, and even every private perfon, undertaking it at pleafure; which renders their money exceedingly bad, and their commerce very unfafe. See Morocco.

Coinage, *Mufcovite.*—The czar Ivan Vaffilievitch inftituted the firft regular coinage, towards the middle of the fixteenth century, and fet up a mint at Mofcow. In the reign of this prince the Ruffian coinage began to acquire a new form, and coins of different denominations were ftruck after a certain alloy and weight. Peter I. made various alterations in the coinage. All mints were abolifhed, except thofe at Mofcow. A mint was afterwards fet up at Peterfburg. and this is at prefent the only one where gold and filver coins are ftruck. At this time there are in Ruffia one mint for filver, and fix for copper coin. See Russia.

Coinage, *Perfian.*—All the money made in Perfia is ftruck with the hammer; and the fame may be underftood of the reft of Afia and America, and the coafts of Africa, and even Mufcovy; the invention of the mill not being yet gone out of Europe, nor even eftablifhed in every part of it. The king's duty, in Perfia, is feven and a half per cent. for all the monies coined; which are now reduced to filver and copper; there being no gold coined there, except a kind of medals at the acceffion of a new fophi.

Coinage, *the Spanifh,* is efteemed one of the leaft perfect in Europe; it is fettled at Seville and Segovia, the only cities where gold and filver are ftruck. It is true, there are brought from Mexico, Peru, and other provinces of the Spanifh America, fuch vaft quantities of pieces of eight, and other fpecies both of gold and filver, that, in this refpect, it muft be owned, there is no ftate in the world where fo much money is coined, as in that of the king of Spain. See Spain.

To take the reprefentation of a coin on paper, card, or pafteboard. See Medal.

CO-INDICATIONS, in *Medicine,* figns which do not indicate by themfelves alone, but together with other circumftances, &c. help the phyfician to form a judgment.

COINING, in the *Tin-works,* is the marking of the tin, when caft into blocks, or flabs, with the figure of the lion rampant. This is done by the king's officer. The king's cuftom is four fhillings for every hundred weight.

COINTE, Charles Le, in *Biography,* was born at Troyes in the year 1611. After having received a good education, he was employed in inftructing others in grammar, the claffics, and rhetoric. He had not devoted many years to this occupation before he was called to affift in diplomatic affairs, and in 1643, he rendered his country confiderable fervice, in conjunction with M. Servien, at Munfter, in fettling the preliminaries of peace. For his zeal and fidelity in this bufinefs he was rewarded with a penfion, which enabled him to devote his whole time to theological ftudies. Between the years 1665, and 1679, he publifhed his great work, entitled "Annales Ecclefiaftici Francorum," in eight folio volumes. This vaft compilation contains almoft every thing

thing that relates to the Gallican church, previoufly to the period in which he wrote. He died at Paris, where he had [illegible] the laft thirty years of his life, in the year 1681, regretted by his numerous friends, as well for the excellence of his character, as for his talents, which, though not of the [illegible]r, he had rendered ufeful to his country and the in[illegible]. Nouv. Dict. Hift. Du Frefnoy.

COIPATLIS, in *Botany*, Hernand. See CALEA *oppofitifolia.*

COIR, in the *Manufactures*, the Afiatic name of a ftrong vegetable fibre, prepared from the hufks of the cocoa-nut, and much ufed in the Eaft Indies in the manufacture of cables and cordage. Dr. William Roxburgh, a correfponding member of the Society of Arts, London, refiding at Calcutta, in 1801, [illegible]mitted to that learned body, the detail of his experiments on hemp, and twenty other different forts of vegetable fibre, with the view of afcertaining their relative ftrength, when white, when tanned, and when tarred; thefe will be found in the 22d volume of their Tranfactions. In 1805, the fame ingenious gentleman tranfmitted to the fociety the refults of his further experiments, on the above mentioned 21 vegetable fibres, in the three ftates above named, both when frefh, and after 116 days maceration in water, during the hot feafon; thefe were for afcertaining the effects of tanning and tarring ropes made of thefe fubftances, both as the fame affected their ftrength at firft, and preferved them from decay by wet. See Tranf. Soc. Arts xxiv. 143.

COIRE, or CHUR, in *Geography*, a town of Swifferland, in the department of the Grifons, fituated at the foot of the Alps, in a rich plain between two and three miles wide. This town lies partly in the plain, and partly upon the fteep fide of a rock, and is furrounded with ancient brick walls, ftrengthened with fquare and round towers, according to the ftyle of fortification before the invention of gun-powder; the ftreets are narrow and dirty; it contains about 3000 perfons. It probably owes its origin to the emperor Conftantius, who, in the 355th year of the Chriftian era, penetrated into Rhætia, and fixed his ftation for fome time near the fcite of this town, which was conftructed near the camp, and deriving from the imperial refidence the name of Curia, its appellation was afterwards changed into Coira and Coire. The remains of two or three towers, evidently of Roman conftruction, atteft its antiquity, and ferve to eftablifh the truth of the above-mentioned conjecture concerning its origin. Coire was formerly a city of the German empire, fubject to its own courts, and in the ninth century became fubject to the dominion of the bifhop. Like many other cities of Germany, it obtained confiderable privileges from the different emperors; and the inhabitants, having gradually circumfcribed the authority of the bifhop, at length eftablifhed an independent republic. The government of Coire is arifto-democratical; the fupreme legiflative authority refides in the citizens, whofe number amounts to 294, divided into five tribes. The executive power is entrufted to the council of 70, compofed of 14 members annually elected from each tribe. This council is divided into feveral leffer departments, the chief of which is the fenate, or council of fifteen, who have the principal direction of affairs, either folely or conjointly with other members of the fovereign council. The chiefs of Coire are two burgomafters, taken from the members of the fenate, who continue in office for life, though liable to a removal. They enjoy the fupreme dignity by rotation, each for a year. The criminal tribunal is compofed of the fenate and 15 other members of the fovereign council. The prifoners are examined and the procefs drawn up by a fecret council, formed of the feven eldeft members of the fenate, the majority of whom muft concur to order the infliction of torture. After the conviction, procefs is laid before the criminal tribunal, which ultimately paffes fentence, and all offences, excepting great crimes, are commonly punifhed by fines. Coire fends two deputies to the general diet of the Grifons, held here every three years. Thefe are generally the two burgomafters. Upon the higheft part of the town ftands the bifhop's palace, the cathedral, and the houfe belonging to the chapter.

The bifhopric of Coire was probably erected foon after the firft eftablifhment of Chriftianity in thefe parts, under Conftantine, or his fon. The diocefe once extended over the whole Roman province of Rhætia, which comprehended the prefent country of the Grifons, the Valteline, Chiavenna, and Bormio, together with the eaftern diftrict of Swifferland as far as the lake of Conftance, and part of Tyrol; the bifhop's territorial poffeffions were alfo confiderable, and his revenues by no means inadequate to his power and dignity. The principal diminution of his power was occafioned by the formation of the league of God's Houfe, and the limitation of his prerogatives in 1527. The introduction of the Proteftant religion gave the final blow to his power; for his revenue fuftained great diminution by the lofs of the tythes, which were feized by the reformed communities. The bifhop is fuffragan of Mentz, and prince of the Roman empire, which dignity was annexed to the fee in 1170 by the emperor Frederic I., and he is ftyled lord of Furftenberg and Furftenau. His annual revenues, which amount to about 2,000*l.*, arife chiefly from eftates near Coire, and in the Tyrol; he receives alfo the annual fum of about 70*l.* from the cuftoms of Chiavenna, in return for having ceded his claims over the Valteline, Chiavenna, and Bormio, to the republic of the Three Leagues. The only prerogatives remaining are the right of coining money, and an abfolute jurifdiction both in civil and criminal affairs within the fmall diftrict in which his palace and the chapter are fituated. The bifhop is chofen by the chapter. The epifcopal diftrict is only a few hundred paces in circumference, and is furrounded by high walls; the greater part of the palace is modern, except a fquare tower, fuppofed to have been conftructed by the Romans. The chapter confifts of twenty-four canons, fix of whom are refident; the inhabitants of this diftrict are all Catholics. Above the palace, and at the higheft extremity of the town, is the convent of St. Lucius, deriving its name from a fmall chapel dedicated to that faint, who, according to the legends of the Romifh church, was a king in Britain towards the latter end of the fecond century. After embracing Chriftianity he is faid to have quitted his throne, and, wandering in thefe parts, to have built an hermitage upon the fpot where the chapel now ftands; and by his preaching and example, to have converted numbers to the Chriftian faith. He is ftyled the apoftle of the Grifons, and held in high veneration as a faint by the Catholics; while the Proteftants of the town pay him not the leaft veneration.

There is a Latin feminary at Coire for the children of the burghers, and another, inftituted in 1763, for the education of perfons intended for the church; thefe eftablifhments, though poorly endowed, have been of fome literary advantage to the country. Coire has alfo a typographical fociety for Latin, German, and Romanfh.

The environs of Coire are delightful; the plain is richly diverfified with corn and pafture, the hills gradually floping to the foot of the mountains are covered with vines, which yield wine of a pleafant flavour, but not ftrong. The Rhine, which flows rapidly through the plain, begins here to be navigable by rafts, and merchandize is tranfported towards Lindau and Zuric. N. lat. 46° 54'. E. long. 9° 29'.

COISLANS, a Dutch factory on the coaſt of Malabar; 23 leagues N.W. of Cape Comorin.

COISLIN'S MSS., *Codices Coiſlini* [illegible] take their name from Coiſlin, biſhop of Metz, to whom they were bequeathed by the celebrated chancellor Seguier, who died in 1672. They are preſerved at preſent in the Benedictine library of St. Germain des Prez, and are deſcribed in the following ſcarce work, *viz.* "Bibliotheca Coiſliniana, olim Seguieriana, ſeu MStorum omnium Græcorum, quæ in ea continentur, accurata deſcriptio, ubi operum ſingularum notitia datur, ætas cujuſque MSti indicatur, vetuſtiorum ſpecimina exhibentur, aliaque multa annotantur quæ ad palæographiam Græcam pertinent, Studio et opera B. de Montfaucon, Pariſiis. 1715. fol." They are likewiſe enumerated in Montfaucon's "Bibliotheca bibliothecarum," tom. ii. One of theſe MSS. is referred by Montfaucon and Wetſtein to the 7th century; others of them were written in the 11th, 12th, and 13th centuries; and moſt of them were brought from mount Athos. One of them contains a part of the O. T. without any proper reference to the N.; five contain the four Goſpels; others contain the Acts of the Apoſtles, and the Catholic Epiſtles; various commentaries on St. Matthew and St. Mark; commentaries on the Acts of the Apoſtles; the Epiſtles of St. Paul, with commentaries; the whole N. T.; the N. T., except the book of Revelations; the Acts, Epiſtles, and Revelations; fragments of the Epiſtle of St. Paul; and the Acts, Epiſtles, and Revelations. From 14 of theſe MSS. Wetſtein, in his N. T. has made extracts. See Marſh's Michaelis, Introd. to the N. T., vol. ii. and iii.

COITER, Koyter, Volcher, in *Biography*, a celebrated phyſician, ſurgeon, and anatomiſt at Groningen, where he was born in the year 1534; ſhewing early a diſpoſition to the ſtudy of medicine, he was ſent by his father to Padua, and placed under the direction of Fallopius, by whom he was initiated into the knowledge of anatomy, in which he was further improved by Euſtachius, during a reſidence of ſome months at Rome. He then went to Bologna, and was introduced to the celebrated naturaliſt, Aldrovandus, with whom he continued his ſtudies. Not ſatisfied with his attainments, he went to Montpellier, and afterwards, with the view of obtaining a greater number of human ſubjects for diſſection, for he had hitherto operated principally on brute animals, he accepted the poſt of one of the phyſicians to the army of the king of France, which he attended through a campaign. The numerous obſervations he made on the effects or alterations produced by certain diſeaſes, in the ſtructure of the viſcera, ſhew how well he was qualified for this poſt. On quitting the army, he went to Nuremburg, where he ſettled and continued to the time of his death, which happened about the year 1576.

Though his life was ſhort, yet, from the activity and powers of his mind, he was enabled to make conſiderable improvements, both in anatomy and ſurgery; among the former are to be noted, his obſervations on the brain, the motion of which, he found, was occaſioned by the motion of the arteries. He alſo diſcovered that the brain was not abſolutely neceſſary to life, which in ſome animals remained after it was taken away. He firſt deſcribed the corpora lutea, in the ovaria; alſo the order in which the parts of the chick are unfolded in the egg; and in the heart he obſerved, that the contraction of the ventricle preceded that of the auricle. He deſcribed the frontal ſinuſes; and though he did not diſcover any of the parts of the organ of hearing, that had not been before noticed, they are more accurately deſcribed by him, Douglas obſerves, than they had been by any preceding writer. He added two muſcles to the face, which are called by anatomiſts corrugators of the eye-lids, but from their uſe, Douglas ſays, they might more properly be called depreſſores ſuperciliorum; alſo two muſcles performing a ſimilar office for the lips. Among his chirurgical obſervations, are, that wounds or hurts of the brain are more dangerous when the dura mater remains entire than when it is ruptured; in theſe caſes, he boldly opened that membrane, to give vent to the effuſed humour. When fungi from the brain ariſe, they may be ſafely, he ſays, pared down. He cured a patient of a wound in the brain, extending to the ventricle but the patient was ever after afflicted with alienation of his mind. The works in which theſe, and numerous other valuable obſervations are contained, are "De cartilaginibus tabulæ quinque," fol. Bononiæ, 1566. "Externarum et internarum principalium corporis humani partium, tabulæ atque anatomicæ exercitationes, obſervationeſque variæ novis et artificioſiſſimis figuris illuſtratæ," Norib. 1573, fol. In the introduction he gives a brief hiſtory of anatomy, and traces the order in which it ſhould be ſtudied. He here firſt gave a complete ſet of plates, depicting the ſkeleton of a fœtus. "Diverſorum animalium ſceletorum explicationes, cum lectionibus Fallopii de partibus ſimilaribus," Norib. 1575, fol. containing well depicted ſkeletons of various quadrupeds, birds, and amphibious animals. Boerh. Math. Studii Med. Douglas Bib. Anat. Haller Bib. Anat., &c.

COITION, the intercourſe between male and female in the act of generation. It is obſerved that frogs are forty days in the act of coition. Bartholine, &c. relate that butterflies make an hundred and thirty vibrations of the wings in one act of coition.

Coition is alſo ſometimes uſed for that mutual attraction, or tendency toward each other, which is found between iron and the magnet.

COIT-MOSS-Colliery. This mine is ſituated near the borders of Cheſhire, and to that ſingular mountain Axe Edge, in the neighbourhood of Buxton, in Devonſhire, which is formed by the weſtern edge of the ſilicious grit rock, covering the lime-ſtone, in this diſlocated part of the country. The ſurface, for a conſiderable diſtance round the pit, is moſs or bog, and which extends ſeveral feet beneath the ſurface; the coal lies from 30 to 40 fathoms deep, and is covered by a ferruginous clay ſchiſt, which decompoſes on expoſure to the air. This mine is drained by a ſough of conſiderable length, in an eaſterly direction.

COJUMERO, in *Zoology*, the name given by ſome to the manati. See Trichechus *manatus*.

COIX, in *Botany*, (Κοιξ, Gr. a name given by Theophraſtus to one of his Καλαμοφυλλοι, or reed-leaved plants, allied to the palms.) Linn. Gen. 1045. Schreb. 1405. Willd. 1638. Juſſ. 34. Vent. 2. 112. (Lachryma Job. Tourn. 306. Lithagroſtis. Gært. Larmille. Encyc.) Claſs and order, *monœcia triandria*. Nat. Ord. *Gramineæ*, Linn. Juſſ. Vent.

Obſ. Gærtner objects to the Linnæan name, as not denoting the plant intended by Theophraſtus and other ancient writers.

Gen. Ch. *Male flowers* in a looſe ſpike. *Cal.* Glume two-flowered, two-valved; valves oblong-egg-ſhaped, obtuſe, awnleſs; the outer one thicker. *Cor.* two valved, valves ovate-lanceolate, nearly the length of the calyx, thin, awnleſs. *Stam.* Filaments three, capillary; anthers oblong. *Female flowers* few, ſituated below the male ſpike. *Cal.* Glume two-flowered, two-valved; valves rounded, thick, ſhining, hard; the outer one larger, ſhining. Linn. Schreb. Mart. Glume one-flowered, one-leafed, ovate-conical, open at its ſummit, fummit, thick, coriaceous, fhining; compofed of two valves, which are united the greateft part of their length. Lam. Glume one-flowered, three-valved; exterior valve larger, thick, coriaceous, fhining; calyx two-valved, fmaller. Juff. Vent. Female flowers two, one conftantly abortive; inclofed in a one-leafed, permanent involucrum, which, as the feed ripens, becomes hard as ftone. Gært. *Cor.* Glume two-valved; outer valve egg-fhaped; inner one narrower, fmaller; both awnlefs. *Pift.* Germ egg-fhaped, very fmall; ftyle fhort, two-cleft; ftigmas two, horned, much longer than the flower, pubefcent. *Peric.* none, except the outer glume of the calyx, which falls off with the feed without opening. *Seed* folitary, roundifh.

Eff. Ch. Male flowers in loofe fpikes. Calyx and corolla awnlefs. Female flowers, calyx and corolla awnlefs. Style two-cleft. Seed covered by the offified calyx.

Sp. 1. C. *lacryma.* Job's tears. Linn. Sp. Pl. Mart. 1. Lam. 1. Willd. 1. Lam. Illuft. tab. 750. (Lacryma Jobi. Cluf. Hift. 2. p. 216. Tourn. 306. J. Bauh. 2. p. 449. Dod. Pemp. 506. Lob. Ic. 44. Lithofpermum arundinaceum forte Diofcoridis et Plinii. Bauh. Pin. 258. Moris. Hift. 3. p. 249. Salee. Rumph. Amb. 5. tab. 75. fig. 2. Catrieonda. Rheed. Mal. 12. tab 70. Lithagroftis lacryma Jobi. Gært. tab. 1. fig. 10.) "Seeds egg-fhaped." Linn. "Spikes axillary, feveral, peduncled." Lam. "Culm femicylindrical above, obtufe; flowers naked; fruit egg-fhaped." Willd. *Root* fibrous, annual, at leaft in our climate. *Stems* two or three feet high, leafy. *Leaves* more than an inch broad, alternate, arundinaceous, fheathing, fmooth, with a white midrib. *Flowers* from the fheaths of the upper leaves, in feveral fafcicled unequal racemes, which are fhorter than their refpective leaves. *Seeds* blueifh white, rounded at the bafe, fomewhat pointed at the fummit, very hard, even-furfaced, fhining like pearls. A native of the Eaft Indies, cultivated in Spain and Portugal, where, in times of fcarcity, a coarfe kind of bread is made of its feeds, and eaten by the poor. It is applied to the fame purpofe in the Levant, and in China. Its feeds are fometimes bored and threaded for necklaces, and other female ornaments. 2. C. *angulata.* Linn. Hort. Cliff. 438. Mart. 2. (C. arundinacea. Lam. 2. Lacryma Jobi Americana altiffima, arundinis folio et facie. Plum. Cat. Lithofpermum arundinaceum alium. Hern. Mex. p. 282. the inner figure?) "Seeds angular." Linn. "Spikes axillary, folitary, nearly feffile." Lam. *Root* perennial. *Stems* feven or eight feet high, hard, branched. Nearly allied to the preceding, perhaps only a variety. 3. C. *agreftis.* Mart. 3. Willd. 2. Lour. Cochin. 551. (Sale-Utan. Rumph. Amb. 6. 22. tab. 9 fig. 1. Lacryma Jobi paludofa minor; Burm. Zeyl. 138.) "Culm quite fimple; leaves even-furfaced; feeds roundifh." Lour. "Culm cylindrical; flowers naked; feeds roundifh." Willd. *Root* perennial, creeping. *Culms* three feet high, cefpitofe, folid, jointed. *Leaves* lanceolate-linear, acuminate, alternate, fheathing. *Peduncles* long, three or four together from the fame axil, erect, many-flowered. *Seeds* brown, fhining, fmall. A native of moift places in Ceylon, Amboina, and Cochin-china. 4. C. *arundinacea.* Willd. 4. Koenig. "Culm femicylindrical above, acute; flowers involucred; feeds elliptical." Willd. *Root* perennial. *Stem* very lofty, branched. *Leaves* aculeate-ferrated. *Peduncles* in pairs, furrounded by inverfely egg-fhaped obtufe involucres, which are linear-cufpidate at the tip. *Fruit* four times fmaller than that of C. lacryma, white, fhining. A native of the Eaft Indies, near Tranfchaur, but very rare.

Propagation and Culture. The feeds of C. lacryma may be procured from Portugal, and fhould be fown in a moderate hot-bed in the fpring: they may afterwards be tranfplanted into a warm border, two feet at leaft diftant from each other, and will require no farther trouble. C. angulata will not bear the open air in England, but muft be plunged into the bark-bed, where it will produce ripe feeds the fecond year.

COKE, Sir Edward, in *Biography*, a lawyer of great celebrity in the fixteenth and feventeenth centuries, was the only fon of Robert Coke, efq. of Mileham, in Norfolk, a barrifter of confiderable practice. He was born in 1550, and received the early part of his education at the free fchool of Norwich; after which he completed his academical ftudies at Trinity College, Cambridge. From Cambridge he went to Clifford's Inn; and in the following year he entered as ftudent in the Inner Temple. He foon difcovered great penetration, and a folid judgment in cafes that belonged to his profeffion; and we are told by himfelf, that he pleaded his firft caufe in the court of King's Bench, in Trinity-term, 1578. About the fame time, he was appointed reader of Lyon's Inn, an office which he held for three years, during which his lectures were much reforted to; his reputation increafed, and his bufinefs as a barrifter found him ample employment for the exercife of his great talents. In a few years he married the daughter and co-heirefs of John Pafton, efq. with whom he had a large fortune; and by means of her connections, in conjunction with his own abilities, he made the moft rapid advances in his profeffion. He was chofen recorder of the cities of Norwich and Coventry; he was engaged in almoft every caufe of importance at Weftminfter Hall; and was frequently confulted in the affairs of the crown. His property and influence in Norfolk pointed him out as a fit reprefentative of the county; he was accordingly elected member; and, in the 35th year of Elizabeth, was chofen fpeaker of the Houfe of Commons, being at the fame time folicitor-general to the queen; an office which he fhortly exchanged for that of attorney-general.

As fpeaker of the houfe, in the year 1593, he made the three ufual requefts, of freedom from arrefts, of accefs to the royal perfon, and of liberty of fpeech; to which the queen replied, that liberty of fpeech was granted to the commons, but they muft know what liberty they were entitled to; not a liberty for every one to fpeak what he liketh, or what cometh in his brain to utter; their privilege extended no farther than a liberty of *aye* and *no*. That fhe would not impeach the freedom of their perfons; and that fhe would not refufe them accefs to her perfon, provided it were upon urgent and weighty caufes, and at times convenient, when fhe might have leifure from other important affairs.

The death of Mr. Coke's lady, by whom he had ten children, afforded him an opportunity of augmenting the number of his alliances, by a fecond marriage with lady Hatton, the widow of fir Chriftopher, and fifter to lord Burleigh, afterwards earl of Exeter. The marriage ceremony, in this inftance, having been performed with fome irregularities, he was profecuted in the archbifhop's court, and obliged to make the requifite fubmiffion, in order that he might efcape excommunication, and the penalties attached to it.

It has been remarked, that few reigns have produced fo many and able lawyers as that of queen Elizabeth; yet of them all, no one was fo much diftinguifhed as Mr. Coke, whom minifters confulted in all points of difficulty; and who, it is faid, never failed to furnifh them with legal colours for all their proceedings; which, though many of them were very extraordinary, yet being fo guarded, were beheld by the people as juft and honourable.

One of the moft interefting profecutions, which was affigned

affigned to him as attorney-general, was that of the earl of Effex, who, with the earl of Southampton, were indicted for the crime of high-treafon. The attorney-general, "Coke," fays Mr. Hume, "opened the caufe againft him, and treated him with the cruelty and infolence which that great lawyer ufually exercifed againft the unfortunate." At the conclufion of his fpeech he faid that, "by the juft judgment of God, he of his earldom fhould be Robert the Laft, that of a kingdom thought to be Robert the Firft." Almoft immediately after the acceffion of James to the throne, Mr. Coke received the honour of knighthood; and in the July following, fir Walter Raleigh was accufed and profecuted for a fuppofed plot againft government. Sir Edward Coke managed this trial entirely, and difplayed fo much rancour againft the prifoner, as may be deemed not only a great reflection, on his own memory, but even on the manners of the age. Traitor, monfter, fpider of hell, are terms which he employed againft an illuftrious character, who was under trial for life and fortune, and who defended himfelf with an even temper and heroical courage. Nor was the attorney-general lefs blameable with refpect to the high court before whom he ftood; his arrogance was fo confpicuous, that lord Cecil demanded, *if he came thither to direct them?* Upon which he fat down, and refufed to utter another word, till he was folicited by all the commiffioners, when he rofe, and recapitulating his arguments, fir Walter was found guilty.

On the difcovery of the gun-powder plot, fir Edward Coke obtained great credit for the fagacity and vigilance which he fhewed in unravelling the facts relating to that extraordinary affair. Upon one of the trials a high compliment was paffed upon him by lord Cecil, who faid, "that the evidence had been fo well diftributed, and opened by the attorney-general, that he never heard fuch a mafs of matter, better contracted, or made more intelligible to a jury." It was in reward for his fignal fervices on this occafion, that he was raifed to be chief juftice of the court of Common Pleas, an office which he appears to have filled with high reputation and honour. In 1613, he was made chief juftice of the King's Bench, and one of the members of the privy council, but without enjoying any confiderable portion of the king's confidence. He had already chofen as his motto, "lex tutiffima caffis;" and it was a maxim to which he determined to adhere; he was, therefore, ill fitted to ferve the high prerogative notions of James; he alfo fhewed marks of indignation, when his fovereign, through the attorney-general, undertook to find out his opinion of a caufe likely to be brought before him as judge; declaring, that it was a principle from which he would not depart, "that he was a judge in a court, and not in a chamber." As his temper had nothing in it that was conciliating, and as he felt the dignity of his high office, which he confidered as held for the benefit of the people, rather than for the pleafure of the crown, he involved himfelf not unfrequently with a court governed by favourites, and fond of a higher degree of power than was allowed by the conftitution. When the earl of Somerfet's guilt in the murder of fir Thomas Overbury was difcovered, the king fent to the chief juftice, fir Edward Coke, and earneftly recommended to him the moft rigorous and unbiaffed fcrutiny; an injunction which he executed with the greateft induftry and feverity. With the fmall clue given him, he unravelled moft carefully the whole labyrinth of their guilt; but his zeal on the trials of the perfons concerned in this affair, was mingled with a bitternefs and fury that feem to have ill accorded with the decorum and dignity of a judge. On the trial of Mrs. Turner, Coke fcrupled not to affirm that fhe was guilty of the feven deadly fins; fhe was a whore, bawd, a forcerer, a witch, a papift, a felon, and a murderer. In the fummer of 1616, he was fufpended from his office, and from his feat at the council board, the occafion of which was owing to fome difference with the new favourite, Villiers, afterwards duke of Buckingham; but in little more than a year, he was received at court, and reinftated in the privy council. He now took an active part in profecuting various perfons for corruption in office, and other offences, by which means many heavy fines were levied, and the treafury replenifhed. In this he feemed to favour the interefts of the crown; but in parliament, of which he was a diftinguifhed member, he maintained the rights and privileges of the commons, againft the proclamations of the fovereign; and was, on that account, in the year 1621, committed to the Tower, and his papers feized. He did not long remain a prifoner, though he was again expelled from the privy council, and ftigmatized by the king, as "being the fitteft inftrument for a tyrant that ever was in England;" a character to which he had no juft title, nor would it have been applied to him by James had he become fuch an inftrument in his own hands.

In the fucceeding reign he was nominated fheriff of Buckinghamfhire, to prevent him from being chofen member of the houfe of commons; he was, however, elected to reprefent that county in the parliament which met in the year 1628, and was diftinguifhed for his zeal in attempting to redrefs the grievances, and fupport the rights and liberties of the people. The moft important fervice which he rendered to his fellow citizens, was in framing and propofing the "petition of rights;" this was the laft of his public acts, and was juftly efteemed the moft explicit declaration of Englifh liberty which had, at that time, appeared. Parliament was in a very fhort time after diffolved, and fir Edward Coke retired to his feat in Buckinghamfhire, where he ended his days in tranquillity, and in high eftimation and refpect. He died September 3, 1634, in the eighty-fifth year of his age, leaving behind him a numerous family, and a very large eftate. In his laft moments he exhibited the utmoft refignation to the divine will, and finifhed his courfe with uttering the words, "thy will be done."

The character of this great lawyer has been varioufly reprefented; but it cannot be denied that he was at once a zealous and faithful fervant of the crown, maintaining its juft prerogatives; and as a fenator, he exhibited a laudable zeal for correcting abufes, from which nothing could ever deter him. His works are, "Reports," in 13 parts, folio. "A Book of entries." "Inftitutes of the Laws of England;" confifting of, (1.) a tranflation and a comment upon fir Thomas Littleton's Tenures; which is his moft celebrated work, and contains an immenfe body of legal erudition: (2.) Magna Charta, and other felect ftatutes, with a comment: (3.) The Criminal Law, or Pleas of the crown: (4.) An account of the jurifdiction of all the courts in the kingdom. "A Treatife of Bail and Mainprize." "Reading on the State of Fines, 27 Ed. i." Complete copyholder. Biog. Brit. Hume.

Coke, or *Coak*, denotes pit-coal or fea-coal charred. For the exciting of intenfe heat, as for the fmelting of iron-ore, and for operations where fmoak would be detrimental, as the drying of malt, foffil coals are previoufly charred, or reduced to coaks, that is, they are made to undergo an operation almoft fimilar to that by which charcoal is made. By this procefs coals are deprived of their volatile parts, nothing remaining except the carbon and earthy impurities. The great quantities of coal duft, or fmall coal, collected at the numerous pits in the neighbourhood of Newcaftle, would foon become a great incumbrance, were it not that an admirable method has been difcovered, not only to prevent the inconvenience,

venience, but to turn it, with a little modification, into an article of commerce and advantage, by preparations as simple as they are ingenious. Coal, in this pulverized state, is not proper for chamber fires, because it falls through the bars of the grates, or extinguishes the fire by falling upon the ignited cinders, in such masses that no air can get between to assist the [illegible] is small coal is, therefore, proper in this [illegible] or some purposes in glass-houses, lime or brick [illegible]. The consumption for these purposes is [illegible]rable, but is not nearly equal to the quan[illegible] the pits, notwithstanding the great care [illegible]o keep the coal in large pieces; besides, some [illegible] to crumble into small-coal upon receiving the least shock: m[illegible]ns have, therefore, been sought to render this coal proper for oth[illegible]rposes. That property, which belongs to the best coal, of agglutinating and forming a single mass, when in a state of combustion, naturally suggested the idea of endeavouring to consolidate considerable quantities of this coal dust, or small-coal, by means of a great fire. To effect this it is put into a kiln, in a great degree similar to a lime-kiln, which is previously well heated with large pieces of coal. The small-coal then runs together, and forms a mass, without losing any large portion of its valuable qualities. When the ignited mass is completely red, large pieces of it are pulled out with iron rakes (such as are used in the copperas works), and laid separately on the ground, where they are very soon extinguished; these pieces are firm, though porous, and are excellently adapted for smelting iron, and other ores, in high furnaces. This simple and ingenious contrivance has given birth to several new branches of industry and commerce. The coal, thus prepared, is used in a great number of manufactories, where a draft or blast is used, as a substitute for charcoal, to which it is in most instances superior, as it produces a stronger, more equal, and longer continued heat. Such is the method of coak-making at Newcastle, and other places. That pursued in the great iron-works at Carron, near Falkirk, in Scotland, being so completely different, our readers will excuse our giving an account of this also. The business is conducted there in the open air, and in the most simple manner; a quantity of large coal is placed on the ground in a round heap, of from 12 to 15 feet in diameter, and about two feet in height; as many as possible of the large pieces are placed on their ends, to form passages for the air; above them are thrown the smaller pieces and coal dust, and in the midst of this circular heap, is left a vacancy of a foot wide, where a few faggots are deposited to kindle it. Four or five apertures of this kind are formed round the ring, particularly on the side exposed to the wind; there is, however, seldom occasion to light it with wood, for other masses being generally on fire, the workmen most frequently use a few shovels of coal already burning, which acts more rapidly than wood, and soon kindles the surrounding pile; as the fire spreads the mass increases in bulk, puffs up, becomes spongy and light, cakes into one body, and at length loses its volatile parts, and emits no more smoke. It then acquires an uniform red colour, inclining a little to white, in which state it begins to break into gaps and chinks, and to assume the appearance of the under part of a mushroom; at this moment the heap must be quickly covered with ashes, of which there is always a sufficient provision around the numerous fires, where the coak is prepared. This method of throwing a large quantity of ashes on the fire, to deprive it of the approach of air, is similar to that used in making charcoal, which is covered over with earth; the result is also pretty much the same, the pit-coal thus prepared being light and porous, and producing the same effect in high furnaces as charcoal. This is a quality of extreme value: since, by means of charred pit-coal, founderies may easily be established, in places where the want of wood for charcoal, would otherwise render it necessary to abandon even the richest mines of iron.

The simple method above described being found to consume much of the best qualities of the coke, owing to the too free access of air during the process; many years ago a method was introduced, of distilling, or charring coals in close vessels, by the heat of another fire externally applied, and by which also the liquid bituminous matter, or coal-tar, was separated and condensed; the value of which, as a substitute for paint in rough works, contributed to render this a profitable mode of preparing strong cokes, for the smelting of metals, and other purposes in the arts, where, with greater plenty of wood, charcoal formerly was used; and which coke, from its superior inflammability, could be used in common grates and stoves, where the draft or influx of air is insufficient to burn the common coke. On the 13th of November, 1800, Mr. David Mushet of Glasgow took out a patent for various improvements in metallurgy, and, among others, for an improved coking furnace, built of fire-brick, or iron-plates, and made to exclude the external air from the coals to be coked while they are heated to incandescence, by a fire underneath with flues enveloping the coking vessel. In his specification (see Repertory of Arts, xiv. 182.), different constructions of these furnaces are described, some to condense the tar and soot, or lamp-black, and some for letting these escape, if their condensation should not be found advantageous. On the 18th May, 1804, Mr. Frederick Albert Winsor took out a patent for combining the saving and purifying of the inflammable gas (for producing light and heat), the ammonia, tar, and other products of pit-coal, with the manufacture of a superior kind of coke (see Repertory, 2d Series, v. 172). And, lately, the same gentleman has taken out a second patent, for further improvements in these processes, but this specification not being yet filed (June 1807), we are unable here to describe minutely, and give drawings of the oven, or carbonizing furnace, as we wished to do, which he uses for preparing his patent coke, of a superior quality, as the residuum of the gas, ammonial liquor, and oil-tar, separated in his processes (see GAS *lights*, and TAR *coal*), in which 300 yards in length of the wall of Carlton-House gardens, next to the Mall in St. James's Park, were, on his majesty's birth-day evening last, lighted up with gas-lamps, and burners, of various constructions, and with transparencies, and other devices, illuminated by brilliant gas-lights. This patent coke, from the experiments which we have seen, seems perfectly applicable to burning in our rooms and apartments; making a lively and pleasant fire, with a very small degree of draught up the chimney, and producing no smoke. Two pecks of coals, weighing 36 lb. coked in one of Mr. Winsor's small carbonizing furnaces, produced $24\frac{1}{2}$ lb. of coke (or 67 per cent.), which, when broke into moderate sized pieces, measured three pecks. Dr. Watson obtained 58, Mr. Jars 63, and M. Hielm 73 per cent. of the weight of coals, in similar experiments.

In the smelting of ores in Silesia, it was found (1. Bergm. Journ. 1790. p. 320.) that 92 lb., or one measure of cokes, were equivalent to 180 lb., or three measures of charcoal; and, in another place (ibid. 1792. p. 60.), one measure of cokes is said to equal the effects of five measures of charcoal, or three of pit-coal.

From the experiments of M. Lavoisier, in the Stockholm Memoirs, 1781, p. 187, it appears, that the heats produced, as measured by the evaporation of equal quantities of water, under equal surfaces, and the times of consumption, to produce

duce the same effect by four different kinds of fuel, were as follow, *viz*

Combustibles.	Weight.	Measure.	Duration.
Pit-coal,	600 lbs.	10 cubic feet.	20 hours.
Cokes,	403	17	$12\frac{1}{2}$
Charcoal,	600	40	5
Oak wood.	1089	33	4.4

Whence it appears, that if coal produces a certain quantity of heat in a given time, coke, in a much smaller quantity, will produce the same effect in little more than half the time; an equal weight of charcoal in one-fourth of that time; and oak wood, of nearly double the weight of coal, in about one-fifth of that time.

The coke-ovens, mentioned in a former part of this article, began about 30 or 40 years ago to be applied to other purposes besides the making of coke. About the year 1780, we remember to have seen a coke-oven, opening with a door almost like a large baker's oven, applied to heating the boilers of the steam-engines of the Chelsea or Pimlico water-works, but which has long since been disused. On the 23d June 1789, the right honourable Henry Seymour Conway took out a patent (see Repertory of Arts, iii. 75.) for improved methods of conveying and adapting the heat of coke ovens to the working of steam engines, baking of bread, calcining and fusing of metals and ores, &c. We are told in this specification, that three biscuit-ovens were erected and worked from the fire of one coke-oven thus constructed, the heat from it being regulated by openings and registers, with perfect success. See Oven. Others of these coke-ovens were adapted for heating boilers, and for working stills.

The earl of Dundonald's method of making cokes, or cinders, after he had extracted the coal-tar from coals, for which he obtained a patent, 30th April, 1781, and the time of which was afterwards extended by act of parliament to the 1st of June 1806, required the admitting of the external air into his furnace, in sufficient quantities to carry on the combustion of the coals operated upon (see Repertory of Arts, i. 145.), by which the necessity of a second, or external fire, for heating the furnace was avoided; but the cokes, produced by this means, are inferior in quality to those produced in close vessels, as in the processes of Muthet, Winser, &c. above mentioned.

COKER, in *Geography*, a river of England, in the county of Lancaster, which runs into the Irish sea, 5 miles N.W. of Garstang.

CO-KIANG, a town of China, of the third rank, in the province of Se-tchuen; 20 miles E.S.E. of Tche-li-keou.

CO-KING, a city of China, of the first rank, in the province of Yun-nan; 1160 miles S.S.W. of Pekin. N. lat. 26° 35′. E. long. 99° 16′.

COKZIM. See Choczim.

COL, or Coll, one of the western islands of Scotland, about 13 miles long, and 3 broad. Col, says Dr. Johnson, is one continued rock, of a surface much diversified with protuberances, and covered with a thin layer of earth, which is often broken, and discovers the stone. Such a soil is not adapted to plants that strike deep roots, nor do they rise to any great height. The uncultivated parts are cloathed with heath, among which industry has interspersed spots of grass and corn; but no attempt has yet been made to raise a tree. The lord of Col has lately introduced the culture of turnips, to provide food for his cattle in the winter. This island has many lochs, some of which have trouts and eels. The quadrupeds are horses, cows, sheep, and goats. It has neither deer, hares, nor rabbits. Rats are its only vermin, and they have been brought thither by sea; they have no serpents, frogs, or toads. The number of inhabitants is estimated at somewhat more than 800. It is 11 miles N.W. from the island of Mul. N. lat. 56° 38′. W. long. 6° 3′.

Col of Arez, a passage of the Pyrenees, in the road from Prats de Molo, in France, to Campredo, in Spain.

Col of *Argentiere*, a passage of the Alps, between Nice and Saluzzo.

Col *de Balme*, an eminence of the Alps, in the vicinity of Mont Blanc, lying in the way from Trient to Chamouny. It is very steep, but not dangerous, and the path, which is in no point bare rock, runs through a thick wood cloathing the sides of the mountain.

Col of *Limon*, a passage of the Alps, between Sospella and Coni.

Col of *Paracols*, a passage of the Pyrenées, between Ceret, in France, and Ampurdan, in Spain.

Col of *Pertus*, a passage of the Pyrenées, between Boulou and Junquere.

Col of *Tenda*, a passage of the Alps, between Piedmont and Nice, over the mountains of Tenda.

COLA dell'Amatrice, in *Biography*, a painter and architect, so called from the place of his birth, a small town near Aquila, in the state of Naples. At Ascoli, and in all that province, where he spent the latter part of his life, Cola enjoys the reputation of having been an excellent painter, as well as a great architect. In some of his early pictures, there is a degree of dryness in the style, but, in his latter works, his drawing is in a grand taste, and his pictures in every respect worthy of admiration. His most celebrated picture at Ascoli, represents our Saviour distributing the eucharist to the apostles, in the Oratorio del Corpus Domini. His greatest work of architecture is the façade of the magnificent church of St. Bernardino, at Aquila, which was begun in 1525, and finished in 1542; it bears this inscription on the architrave: Cola. Amatricius. Architector. Instruxit. This artist is likewise spoken of as a sculptor. Lanzi. Storia Pitt. Milizia. Mem. degli Arch.

Cola, Gennaro di, one of the painters who flourished in Naples in the 14th century. He was born about 1320, and was the scholar of Maestro Simone, an artist of some eminence in the city. There are several stories of the life of the Madonna, painted by this master, in company with another Neapolitan painter called Stefanone, in the church of St. Giovanni da Carbonara; they are executed with great diligence. This artist died about the year 1370. Lanzi. Storia Pitt. Domenici.

COLAIR Lake, a lake of Hindoostan, which, during the inundations in the season of the periodical rains, is 40 or 50 miles in extent, and at all times a considerable piece of water, and lies about midway between the Godavery and Kistnah, in the new soil gradually formed by the inundations of these rivers, about 12 British miles to the N. of Masulipatam. The origin of this lake may be referred to the same cause as that which produces the lakes and morasses of the Egyptian and Bengal deltas; which is, that the deposition of mud by the two rivers (or the two branches of one river) at the time when they overflow, is greatest near the banks; and thus the ground acquires the form of an inclined plane from each river bank towards the interior part of the country, where a hollow space will be left. The subsequent inundations finding their way into this hollow place, from the lower part of the river, will gradually fill up with mud that part of the lake which lies towards the source of it; and as the new land continues to encroach upon the sea, the lake will travel downwards in the same proportion. A plan has been

been propofed for opening a communication at all feafons between the Colair lake and its parent rivers, with a view to the improvement of the adjacent lands, which form a part of the circars, and of the inland navigation. But though the propofal was made in 1779, it does not feem to have been adopted. Rennell's Mem. p. 256.

COLAIRCOTTA, a town of Hindooftan, in the circar of Ellore; 10 miles E. of Ellore.

COL. Ital. *with*, in *Mufic*, a contraction of con-la, con-le, con-lo, as *col baffo*, with the bafe; *col cembalo*, with the harpfichord; *colla parte*, with the voice-part; *coll'organo*, with the organ, &c.

[illegible], a town of India, on [illegible] the Ganges. Ptolemy.

COLÆPIANI, a people of Pannonia, who, according to Pliny, inhabited the country near the Savus; fuppofed to have derived their name from the river Col[illegible]

COLAN, in *Geography*, a fmall town fituated near the South Sea, on the bay of Paita, in the kingdom of Peru, and jurifdiction of P[illegible] [illegible] is town runs the river Chera, the fame ftream which waters Amotape. The inhabitants cultivate grain and breed cattle, with which they fupply Paita, at the diftance of about four leagues towards the fouth, and alfo other towns. The Indians of this town are under an obligation of daily fending to Paita one or two balzas loaded with water, which is diftributed among the inhabitants by ftated proportions. The nature of the foil, and the fituation of the place, render it extremely hot. Its inhabitants, compofing about 35 or 40 families, and confifting of Spaniards, Mulattoes, and Meftizos, live chiefly by paffengers going or returning from Panama to Lima. The town thus owes its whole fupport to the harbour, which is the place where the cargoes of goods fent from Panama are landed, together with thofe coming from Callao to the jurifdiction of Piura and Loja. Here they alfo conftruct large rafts of logs, which will carry 60 or 70 tons of goods: with thefe they make long voyages, even to Panama, at the diftance of five or fix hundred leagues. They bear a maft with a fail attached to it, and they always go before the wind, being unable to ply againft it, fo that they are adapted to thefe feas in which the wind is always nearly in the fame direction. Their cargo is ufually wine, oil, fugar, Quito cloth, foap, and dreffed goat-fkins. The float is commonly navigated by two or three men, who fell their float when they difpofe of their cargo, and return as paffengers to the port from which they came. The Indians go out at night by favour of the land-wind, with fifhing floats, more manageable than the others, though thefe have mafts and fails too, and they return again in the day-time with the fea-wind.

COLANA, in *Ancient Geography*, a town of the Greater Armenia, near the Euphrates. Ptolemy.

COLANCORUM, a town of Germany, according to Ptolemy.

COLANIA, or COLONIA, a town of the ifle of Albion, affigned by Ptolemy to the Damnii, and fuppofed by Camden and Baxter to be the prefent Coldingham; but this being at too great a diftance, and belonging to another nation, others have thought it more probable that it was fituated at or near Lanark, the fhire-town of Clydefdale.

COLANTONIO, MARZIO DI, in *Biography*, a painter of confiderable merit, who flourifhed towards the latter part of the 16th century. He was born at Rome, and was inftructed in the art by his father, an indifferent painter of grotefques. Marzio foon made a rapid progrefs, and excelled in frefco, in which way he was employed, upon many confiderable works, in the churches and palaces of Rome: amongft others he painted a chapel dedicated to St. Andrea, in the church of the Madonna della Confolazione, with ftories of that apoftle. He afterwards painted many fmall pictures of battles and landfcapes, in the ftyle of Tempefta, for which he was much admired. The laft years of his life were fpent in Piedmont, in the fervice of the prince of Savoy. He died in the prime of life, in the pontificate of Paul V. Baglione. Lanzi. Storia Pitt.

COLAPIANI. See COLÆPIANI.

COLAPIS, a river of Pannonia, which difcharged itfelf into the Savus, near Sifcia, according to Pliny: Strabo and Dion Caffius mention this river; but the latter calls it Colops.

COLAPTICE, the art of carving, or cutting, the refemblances and figures of natural things in ftone. The term for the artift is *lithoxos*.

COLAR, in *Geography*, a town of Hindooftan, in the Myfore country; 35 miles E.N.E. of Bangalore, and 135 W. of Madras. N. lat. 13° 9'. E. long. 78° 19'.

COLARBASIANS, or COLORBASIANS, in *Ecclefiaftical Hiftory*, a fect of Chriftians in the fecond century; fo called from their leader, Colarbafus, a difciple of Valentinus; who, with Marcus, another difciple of the fame mafter, maintained the whole plenitude and perfection of truth and religion, to be contained in the Greek alphabet; and that it was upon this account that Jefus Chrift was called the *alpha* and *omega*. This fect was a branch of the VALENTINIANS. See alfo MARCOSIANS.

COLARIN. See COLLARINO.

COLARNI, in *Ancient Geography*, a people of Spain, in Lufitania, according to Pliny. Ptolemy calls their town *Colarnum*.

COLARUS, in *Geography*, a town of Hindooftan, in the circar of Gohud; 30 miles S.S.W. of Narwa, and 125 S. of Agra.

COLATTO, a town of Italy, belonging to the ftate of Venice, in the Trevifan; 6 miles S.S.W. of Ceneda.

COLATURE. See FILTRATION.

COLBA, a town of Germany, in the circle of Upper Saxony, and territory of Neuftadt; 3 miles W.S.W. of Neuftadt.

COLBATCH, JOHN, in *Biography*, an apothecary and furgeon, and in his later years member of the college of phyficians, London, a man of much induftry and ingenuity, and author of numerous publications on medical fubjects. He appears to have practifed medicine in London, and to have been in confiderable repute from the beginning to nearly the middle of the laft century. His firft work was entitled "A New Light of Chirurgery," publifhed in London in 8vo. 1695. He fhews the mifchief occafioned by ufing tents, and injecting acrid fubftances into wounds, and inftead of them recommends a powder of his compofing, which he diffolved in water and applied. It reftrains hæmorrhage, he fays, fooths pain, and difpofes ulcers and wounds to heal. As this excited oppofition, in an edition of the fame work publifhed fome years after he vindicated his doctrine, and adds a variety of cafes and experiments, in which his method had been attended with complete fuccefs. In 1696, he publifhed "A Phyfico-Medical Effay concerning Alkali and Acid," 8vo. He attributes moft difeafes to a predominant alkali in the conftitution, and fays they are to be moft efficacioufly relieved by adminiftering acids. Lemon juice, cream of tartar, and the acid of vitriol, were found by him to be fovereign remedies againft moft difeafes. Among other complaints, they cured the gout, on which he wrote a treatife the following year. His laft publication was on the "Mifletoe of the Oak," London,

don, 1719. He found it efficacious against the epilepsy, chorea sancti viti, and other diseases of the nervous system. He gives half a drachm of the powder of the missletoe, every three or four hours. The book contains full directions for collecting and preparing the plant, which is equally efficacious, he says, gathered from any other tree, as from the oak. His opinion of the efficacy of the plant is confirmed by the recital of several cases in which he had given it with success. Notwithstanding the high character he gives of the missletoe, it has long since fallen into disuse. Dr. Fraser has lately endeavoured to recal the attention of physicians to the subject, but he seems rather to have been led to it, by reading the account given by Colbatch, than from his own experience; at the least, the few cases he recites are not in point. Of the time when Colbatch died we have no account. Haller Bib. Chir. &c.

COLBERG, in *Geography*, a well fortified Prussian town in that part of Pomerania anciently called Cassubia, is situated on the river Persante; which, not far from hence, falls into the Baltic sea, and forms a convenient harbour. It has a few linen and woollen manufactures, a good salmon and lamprey fishery, and a tolerable trade. Some salt is made, on account of the crown, out of a salt spring close to the town. In 1758 Colberg was bombarded by the Russians without effect. Under the command of the brave colonel Loucadou, the garrison opposed an equally successful resistance to the French, who invested the place in November, 1806, and raised the siege in April, 1807. Colberg is distant 98 miles N.N.E. from Kustrin, and 124 N.E. from Berlin. N. lat. 54° 8'. E. long. 15° 27'.

COLBERT, John Baptist, marquis Seignelai, in *Biography*, one of the greatest statesmen that ever had the management of the affairs of France, was born at Rheims, in 1619. His father was Nicholas Colbert, whose family was originally from Scotland. The subject of this memoir shewed an early attachment to commercial and financial pursuits, and to gratify his inclinations, in this respect, he made a tour through the provinces of France, which were the most famous for trade and manufactures. At Paris he was introduced to the prime minister, cardinal Mazarin, who admitted him to his confidence, and in a short time entrusted to his management the most important concerns. The cardinal, during his last illness in 1661, recommended Colbert to his sovereign, as a man qualified for the highest office, and appointed him one of the executors to his last will. Louis XVI. attended to his late minister's recommendation and appointed Colbert as intendant of the finances. He immediately set about reforming abuses, and abolishing a number of useless places which, in that, as in other states, had been created for the purpose of serving individuals, rather than of benefiting the public. He quickly re-established order in the receipts and payments, and by a strict regard to the principles of economy, was enabled to augment the public treasury, while at the same time he actually diminished the taxes imposed on the people. He established a court of justice to examine and decide on all matters relating to finance, and thus recovered many alienations of the revenue, and suppressed annuities to a great amount, which had been acquired unjustly, and for which the original price was repaid. In 1664 he was appointed superintendant of the public buildings, and invited architects, sculptors, and other artists of real eminence, from all parts, whom he employed, on the most liberal terms, to decorate the palaces, and to render the capital worthy of the greatness of the kingdom. It was about this time that he turned his attention to commerce, and by his prudence and activity, raised, as a preparatory step, the royal navy to a most respectable state, so as to enable it to protect the designs which he had in view. He conceived the project of reviving the French East India Company, notwithstanding all the misfortunes which had disappointed the skill and diligence of his predecessors; for this purpose he made himself acquainted with such merchants and seamen as were most conversant with the business. From them he learnt that a scheme of this magnitude could not succeed, without a very large fund established for the purpose: a peremptory exclusion of foreigners; and such a degree of liberty and independence being secured to the company as might be satisfactory to every one, whether native or foreigner, of the safety of the property entrusted to them. To attain these objects it was necessary to give a stimulus to the nation; accordingly the pens of the most able academicians were employed to recommend them to public notice. Colbert succeeded, and he established also the West India and African companies, which gave to France many important advantages. Nor was the minister less attentive to the internal manufactures of the country; those of silk, of wool, of glass, and of steel, were either introduced or liberally encouraged, and fostered by his care and solicitude; and it is said that there was scarcely a year of his ministry in which he did not introduce some new and useful manufacture to excite the industry, and augment the wealth of his countrymen.

Colbert was the zealous patron of the arts and literature; he prevailed upon Cassini to quit Italy, and to place himself under the protection of the king of France, by whom he was pensioned. The French academy of painting was likewise founded by Colbert; he was greatly instrumental in the establishment of the Academy of Sciences, and that of inscriptions took its rise from an assembly in his own house for the purpose of furnishing designs for the king's medals. To encourage national industry he projected the grand canal of Languedoc, thereby uniting the two seas by which France is bounded. This undertaking, which was completed in about fourteen years, has afforded prodigious advantages to the enterprizes of the French nation, which would have been raised to a much higher degree of opulence had not the sovereign's inclination for war, and for expences of every kind, brought on embarrassments, which not only thwarted the designs of the minister, but finally destroyed many of his best plans. He himself has been accused of a too great regard to show and parade, and with a desire of encouraging the industry of towns, to the detriment of the agricultural interests. To render provisions cheap to the inhabitants of towns, and thereby encourage manufactures and commerce, he prohibited the exportation of corn, and thus excluded the inhabitants of the country from every foreign market for the produce of their industry. This great man, after having passed through many offices of the first importance in the state, died of the stone in September, 1683, in the sixty-fifth year of his age, leaving behind him six sons and three daughters. He was a man of great probity, extensive knowledge, in whatever concerned his own situation, and of the most indefatigable industry. His well timed, and necessary reforms, created him enemies, but his name has descended to posterity, accompanied with the plaudits of the wise and good of every nation. Nouv. Dict. Hist. Univer. Hist. Histoire de France.

Colbert, John Baptist, marquis de Torci, and son of the above, was born in 1665. In 1686 he was appointed secretary of state for the foreign department, and in 1699 director-general of the posts. He is said to have surpassed his father in the extent of his abilities and in the cultivation of his faculties: but in imitation of him he was a zealous promoter of commerce and the arts, and raised the French navy

navy to a superiority over every other in Europe. He died in 1746, having attained the reputation of an able statesman, and an excellent man. He left behind him memoirs of the negociations from the treaty of Ryswick to the peace of Utrecht, which were published in 1756 in three vols. 12mo.

COLBERTI's MSS. *Codices Colbertini*, in *Biblical History*, were collected by the celebrated Colbert, minister of the marine to Louis XIV. and are at present in the royal library in Paris, for which they were purchased by cardinal Fleury. They are described in general in the "Bibliotheca Colbertina," Parisiis, 1728, p. ii. 8vo. and in Montfaucon's "Bibliothecarum" tom. ii. But several of Colbert's MSS. and especially those of the Greek Testament, appear to have been separated from those of the Colbert library, and placed among the MSS. which were before in the royal library. The Colbert MSS. of the Greek Testament must therefore be sought among the Codices Regii, in the second volume of the "Catalogue MSS. Bibl. Regiæ." Five of these MSS. which contain the four gospels, of which two are referred to the 11th century, were collated by Simon, and their readings noted in the margin of Curcellæus's edition of the Greek Testament. Of seven other MSS. given in Mill's Greek Testament as eight, that learned critic has given a collection of readings, made by Larroque in a very superficial manner, and communicated by Allix. One of these divided by Mill into three separate MSS. contains the whole New Testament, except the book of Revelation, and was in Mill's time supposed to be 600 years old. This important MS. is described by Griesbach in his "Symbolæ," who defends it against the suspicion of its having been altered from the Latin, relates that its readings harmonize with those of Origen, refers it to the 11th or 12th century, and estimates it as a MS. of great value. Twelve other Codices Colbertini are simply Lectionaria of the four gospels, which Wetstein collated in 1715. See Michaelis's Introd. to the N. T. by Marsh, vols. ii. and iii.

COLBUSA, in *Ancient Geography*, a town of Bithynia. Pliny.

COLCHAGUA, or COLLAGUA, in *Geography*, a town of South America, in the kingdom of Chili, and capital of a jurisdiction containing about 1500 families.

COLCHESTER is a large market and borough town of Essex, England, and, as its name imports, was formerly a Roman station. From an examination of the best authorities it appears to have been the Camalodunum of the Romans; and Tacitus, with some other ancient historians, relate that it was the principal military colony of the legions under Claudius. That emperor, having subjugated the Trinobantes, took possession of this strong hold, and garrisoned it with the second, ninth, and fourteenth legions, whom he flattered with the pompous appellation of "conquerors of Britain," and named the place Colonia; probably as a preeminent memorial of its being the first Roman colony established in this island. In the Itinerary of Antoninus, it is distinguished both by that appellation, and by its original one of Camalodunum. It appears also, from the coins of Claudius, mentioned by Camden, to have been called Colonia-Camalodunum. Claudius, after establishing this colony, reduced the adjacent country into a Roman province; and having appointed Plautius, proprætor, returned to Rome, where a magnificent triumph was decreed to him by the senate, an anniversary solemnity instituted to commemorate his victory, and the surname of Britannicus entailed on his family. His success caused equal rejoicing at Camaloduđum, where a temple was erected to his memory, and he was worshipped as the tutelar deity of the place. This prosperity was not destined to last; for though the oppressed Britons were conquered, they were not subdued; and after several unsuccessful efforts to regain this station, they at length effected it under Boadicea. This Amazonian princess, taking advantage of a favourable opportunity, when the chief part of the veteran legions was withdrawn, directed her force against this devoted colony; fire and slaughter marked her progress; and Camalodunum, the seat of Roman tyranny in Britain, was overwhelmed in its own ruins, after a feeble resistance from the remaining soldiers, who defended themselves for two days in the temple. From the authority of Pliny, and the evidence of Roman coins, with other antiquities, it is, with high probability, deduced that Camalodunum was soon rebuilt.

"There are more Roman remains in and about this town than in any other part of South Britain. Immense quantities of Roman bricks and tiles are to be seen incorporated, or rather are the chief materials in all the most ancient and public edifices. The town-walls, the castle, and the churches are half built with them; and in several parts even the Roman workmanship is copied. The bricks are generally about 14 inches by 13, some 18 by 14; exceedingly hard and well baked. The *supellex Romana* of all kinds still abounds here; hardly any place being dug up, without urns, vases, and pottery of all sorts, or at least, fragments of them being discovered. Sepulchral urns, with the ashes therein, are likewise frequently found; as well as lamps, rings, intaglios, chains, &c. A remarkable sepulchral urn, in particular, was taken up here a few years ago. It was a large vessel, made of thick, coarse, light clay, containing twenty gallons; within was an urn of black earth, holding about two gallons, and having in it the ashes of a Roman lady, as may be supposed, because there were also with it two bottles of clay for incense, two clay lamps, one metal vessel for ointment, and a speculum of polished metal, anciently used for a looking glass." Morant's Essex.

The tessellated pavements are generally found at the depth of between three and four feet beneath the surface. There appear to have been several in the church-yard of St. Mary's at the Wall; tesseræ having been frequently dug up in different places. Many Roman pateræ, fragments of sculptured vessels, sacrificing instruments, Roman bracelets, and other antiquities have also been found here; and lately in a field near the west end of the town, part of a Roman hypocaust was discovered. The continued residence of the Romans at Colchester is farther confirmed by the many strong entrenchments, stretching from north to south, westward of the town. These are conjectured to be the remains of the Castra, Castella, and Præsidia, which, we learn from Tacitus, were formed about this station.

Ancient tradition gives to the town the honour of being the birth-place of Constantine, the first Christian emperor, and his mother Helena; the substance of this legend, which has frequently engaged the attention of the learned, is briefly this; that Coël, a British prince, was invested by the Romans with the government of this district; where, taking advantage of the distraction of the Roman empire, he assumed independence, repaired the public works, and gave his capital the name of Caer-Coel; that Constantius, empowered with sovereign authority by Dioclesian and Maximilian, was sent to Britain to reduce the revolters, and that he laid siege to Caer-Coel as the centre of the insurrection; that during the siege, which continued three years, Constantius became acquainted with Helena, the daughter of Coel, was captivated by her personal charms and mental endowments, and made peace with Coel, on condition of receiving his accomplished daughter in marriage; and that Constantine was the issue of this union, and was born at Caer-

Caer-Coel. This tradition, which originated with British writers, is wholly unnoticed by Roman historians, and contradicted by the concurrent evidence of the best informed writers on Roman history. (See Gibbon's "Decline and Fall of the Roman Empire.") The real birth-place of Constantine is generally supposed to have been Naissus in Dacia. Though the tradition which assigns it to Colchester is found to be unworthy of credit, yet it probably owed its rise to some occurrences in the history of this city, particularly connected with his family. Constantius resided in Britain a considerable time, accompanied by his son Constantine, and probably by his wife Helena; and Colonia being then a flourishing station, he may be supposed to have made it, at least, an occasional residence. Constantius was a secret promoter of Christianity; and Constantine and Helena being avowedly so, obtained the veneration of the inhabitants, who ascribe to her, among other pious labours, the foundation of St. Helen's chapel.

Under the Saxon government, Colchester, then called Colon-ceaster, or Colne-ceaster, lost much of its ancient consequence, by the increased importance of the English metropolis, which arose from its more favourable situation for trade and commerce. The Danes afterwards obtained possession of Colchester, and, by a treaty with Alfred, were established here and in the adjacent country; but recommencing their usual system of destruction and plunder, Edward the Elder laid siege to this town, which was taken by assault, and the Danes were all put to the sword. Edward is supposed to have repeopled the desolated city by a colony of West-Saxons, and in 922, according to the Saxon Chronicle, he rebuilt or repaired the walls. Colchester appears to have been a considerable town at the time of the Domesday Survey; the number of burgesses, who then held houses under the king, was 276; the number of houses in their possession 355, besides many others occupied by different proprietors. At the commencement of the civil commotions in the reign of Charles I., the inhabitants of Colchester coalesced with the parliament and petitioned that the town might be better fortified; in consequence of which 1500*l.* was accordingly granted for that purpose. Unwarranted acts of outrage were soon committed by the lower classes against the Lucas family; but the horrors of civil war were not felt in all their severity till the year 1648, when the memorable siege of this town reduced the inhabitants to the greatest distress.

Colchester is situated principally on the summit and northern aspect of a gentle eminence, rising from the river Colne, which flows on the north and east sides, and is navigable to the spot called the New-Hythe, in the east quarter of the town. The space inclosed by the remains of the ancient walls, forms a parallelogram, having its longest sides towards the north and south; the buildings without the walls, chiefly on the south and east, are very irregularly disposed. The principal street, which runs nearly east and west, contains many respectable houses and large shops; but is disfigured by the old market-house and other small buildings, which, occupying the middle of the street, obstruct the passage. Part of the town was first paved in the year 1473: in the reign of James I. an act was obtained for paving the whole, and its provisions were enforced by another act passed in 1750. By these statutes, the land-owners and proprietors of buildings, are compelled to pave and repair all the ways contiguous to their respective possessions. The preservation of the walls was formerly an object of great attention, but they are now nearly destroyed; and what remains is only kept in repair by those who have gardens or grounds adjoining. The walls consist of stone and Roman brick, united by a very strong cement; their circumference is one mile and three quarters, inclosing an area of rather more than 108 acres. Edward the Elder, as already mentioned, rebuilt or repaired them after the defeat of the Danes in 921; and Richard II. is recorded to have exempted the burgesses from the charge of sending members to three parliaments, on account of the great expence they were at "in repairing their wall with lime and stone against all invaders." Similar exemption was granted by the two succeeding sovereigns; but since the siege in 1648 no public attention has been paid to the walls. When in their perfect state, the entrance to the town was by four principal gates and three posterns; most of which are now destroyed. The walls were strengthened by several bastions, and defended on the west by a small ancient fort of Roman workmanship, constructed with the walls originally called Colkynge's castel; the arches that remain are formed of Roman brick; on the north and west sides were deep ditches in the places most open to attack.

On an elevated spot, north of the High street, and commanding a prospect of the winding valley to the north and east, stand the ruins of a very ancient castle. The outer walls of the keep are nearly perfect, and by their vast thickness and solidity, evince the importance that in the early ages was attached to this situation. The whole building is constructed with a mixture of stone, flint, and Roman bricks; but the latter are chiefly in such pieces as convey an idea of being taken from some more ancient building. The erection of this fortress is ascribed by Norden to Edward the Elder; but the Monasticon refers it to Eudo Dapifer, sewer or steward to William the Conqueror; it is evidently Norman in its general structure; yet it seems probable, from the great number of Roman bricks worked up in the walls, that it was raised on the site of some Roman building, and with a large portion of its materials. The tradition recorded in the Colchester Chronicle, precisely points out a more ancient edifice on this spot; "in fundo palatii Coelii quondam regis;" now if, according to Mr. Gough's supposition, Coel or Coelius was a Roman name, the origin of the fortress seems to be ascertained; and unless some spacious structure had previously occupied this site, there would be great difficulty in accounting for so large a space as the castle and its ramparts include, so near the centre of the town, remaining unoccupied till the time of the Normans. For a more particular account of the castle, vide "Architectural Antiquities of Great Britain," vol. i.

The town and suburbs of Colchester comprehend sixteen parishes; some of the churches are destroyed; the remainder, with the ruins of St. John's abbey, St. Botolph's priory, and the Moot-Hall, constitute the chief of the ancient and public buildings. St. John's abbey, so called from its dedication to St. John the Baptist, was a very magnificent structure, founded by Eudo Dapifer, in the year 1097; it occupied a pleasant eminence without the walls on the south side; but only the entrance gateway, and some fragments of other parts, now remain. The gateway is built with hewn stone and flint, and the workmanship is very uniform and stable. The abbey church was of singular construction, having a tower in the centre, with circular angles, terminated by small conical spires; the west front also was furnished with circular turrets. The abbey had the privilege of sanctuary. At a small distance, north-east, are the remains of St. Botolph's priory, generally supposed to have been founded by a monk named Eynulph or Ernulph, early in the twelfth century; though some portions of the ruins imply a far anterior date. Ernulph was the first prior, and placed on his foundation regular canons of the Augustine order. The priory church, which was parochial as well as conventual, continued nearly perfect till the siege in 1648,

when

when it was in a great meafure deftroyed; the contending parties charge each other with having wantonly occafioned its demolition. Its ruins are peculiarly interefting to the architectural antiquary, as prefenting fome curious fpecimens of brick ornaments, and of interlaced arches, from which the idea of the pointed arch is fuppofed to have originated. The length of this edifice within the walls, was, in its priftine ftate, 108 feet; its breadth, including the naves and ailes, nearly 44. The weft-front was highly decorated; on this fide was the principal entrance, which is ftill extant. The door-way is a fine femicircular retiring arch, having various zig-zag mouldings conftructed with fmall thin bricks and hewn ftone in alternate fucceffion. Thefe venerable remains are particularly defcribed in the "Architectural Antiquities of Great Britain," vol. i.

Eaft of St. Botolph's, is St. Mary Magdalen's hofpital, originally founded for perfons afflicted with leprofy, by Eudo Dapifer, temp. Henry I. To Eudo alfo the Moot-Hall owes its origin, where the courts are held, and the public bufinefs tranfacted. Adjoining to it are the town gaol and theatre. A free fchool and feveral charity fchools have been eftablifhed, and various meeting-houfes built for different religious fects. Colchefter was incorporated by charter of Richard I. dated 1189; and the burgeffes were at the fame time invefted with many valuable privileges, particularly the exclufive right of fifhery on the Colne, from the north bridge to Weft-Neffe. Thefe privileges have been confirmed and extended by feveral fubfequent fovereigns, efpecially by Henry V., the initial letter of whofe charter reprefents St. Helena before the crofs, finely illuminated. The laft charter, under which the town is now governed, was granted by George III. in 1763. Its provifions are nearly fimilar to thofe of the former charters granted by Charles II. and William and Mary, which have on different occafions been furrendered. The corporation confifts of a mayor, recorder, town-clerk, twelve aldermen, eighteen affiftants, eighteen common-councilmen, and fome inferior officers. The right of returning reprefentatives to parliament is vefted in the corporation and free burgeffes not receiving alms; the number of voters is about 1400. The earlieft return was made 25 Edward I.

Colchefter has been a market-town time immemorial; but this privilege was confirmed by Richard the Firft's charter. The market is held on Saturday. The number of inhabitants returned under the late act, as refiding within the town and liberties, was 10,089; the number of houfes 1793. A confiderable portion of the trade of the town arifes from the oyfter fifhery: Colchefter oyfters having been long celebrated for their goodnefs and flavour. This town is diftant from London 51 miles N.E.

Mile End, fo named from being nearly that diftance north of Colchefter, is an extenfive parifh, chiefly belonging to the burgeffes of that town, by a grant either from Henry I. or Stephen, which was renewed by Henry VIII. Morant's Hiftory of Effex, 2 vols. fol. Hiftory of Colchefter, 2 vols. 8vo.

The top of the ftaircafe of St. Mary's church fteeple in this town, was, about the year 1798, felected as one of the ftations in the Government Trigonometrical Survey, and its fituation was determined by an obfervation from Great Tay fteeple diftant 33,056 feet, and bearing 84° 22′ 42″ N.W. from the parallel to the meridian of Greenwich, and another from Stoke fteeple diftant 36,796, and bearing 1° 47′ 26″ N.W. from the fame parallel, whence was deduced its latitude 51° 53′ 17″.7 N. and its longitude 0° 53′ 33″.7 E. of Greenwich. The obfervations from this place were ufed with thofe of Great Tay for fettling the fituation of Weft Bergholt; and with thofe of Stoke, for Earl's Colne and Little Bromley churches. The Colne river is navigable for fmall fea-built veffels up to this town. See Canal.

Colchester, a townfhip of America, in Ulfter county, New York, fituated on the Popachton branch of Delaware river, S.W. of Middletown, and about 50 miles S.W. by S. of Cooperftown.—Alfo, a large townfhip in New London county, Connecticut, fettled in 1701; about 15 miles weftward of Norwich, 25 S.E. of Hartford, and 20 N.W. of New London city.—Alfo, the chief town of Chittenden county, Vermont, fituated on the eaft bank of lake Champlain, at the mouth of Onion river, and N. of Burlington, or Colchefter bay, which fpreads N. of the town.—Alfo, a poft-town of Fairfax county in Virginia, fituated on the N.E. bank of Occoquam creek, three or four miles from its confluence with the Potowmack; and here about 100 yards wide, and navigable for boats. It contains about 40 houfes, and lies 16 miles S.W. of Alexandria, 106 N. by E. of Richmond, and 172 from Philadelphia.

COLCHICUM, in *Botany*, (fuppofed to be fo called from Colchis, where it is faid to grow in great abundance,) Linn. Gen. 457. Schreb. 621. Willd. 707. Gært. 81. Juff. 47. Vent. 2. 155. Tourn. Claff. 9. Sect. 1. Gen. 5. Clafs and order, *hexandria trigynia*. Nat. Ord. *Spathaceæ*; Linn. *Junci*, Juff. *Joncacei*, Vent.

Gen. Ch. *Cal.* a fpathe. *Cor.* monopetalous, tubular, very long, fpringing immediately from the root; border campanulate, deeply divided into fix lanceolate-egg-fhaped fegments. *Stam.* Filaments fix, awl-fhaped, fhorter than the corolla, inferted into the tube; anthers oblong, four-valved, incumbent. *Pift.* Germ fuperior, fituated at the bottom of the tube of the corolla, contiguous to the root, below the furface of the ground; ftyles three, a little longer than the ftamens; ftigmas reflexed, channelled. *Peric.* Capfules three, inflated, coherent in their lower part, flightly feparated towards the fummit, opening longitudinally on the inner fide. *Seeds* numerous, almoft round, wrinkled.

Eff. Ch. Calyx a fpathe. Corolla fix-cleft; tube fpringing immediately from the root. Capfules three, connected, inflated, with many feeds.

Sp. 1. C. *autumnale*. Linn. Sp. Pl. 1. Mart. 1. Lam. 1. Willd. 1. Lam. Ill. tab. 267. Eng. Bot. tab. 133. Woodv. Med. Bot. tab. 177. (C. commune; Bauh. Pin. 67. Moris. fect. 4. tab. 3. fig. 1. Rai. Hift. 1172. Syn. 373.) "Leaves flat, lanceolate, erect." *Root* bulbous, nearly as large as that of the tulip, flefhy, abounding in a milky juice, perifhing after the ripening of the feeds, but firft throwing out a lateral bulbous offset, which produces the flowers of the enfuing year. *Flowers* generally purplifh, opening in the latter end of September without ftem or leaves; tube of the corolla very long; fegments of the calyx, lanceolate, large; anthers yellow; germ remaining under ground during the winter. *Leaves* appearing in the enfuing fpring, a foot long, broad, flattifh, obtufe, dark green, upright, three or four together, fheathing. *Capfules* rifing with the leaves, and ripening the feeds in May. There is a variety, or rather a monftrofity of this fpecies, figured in Englifh botany, tab. 1432. It is produced by fome accidental caufe which prevents the plant from flowering at the proper feafon, in confequence of which the flowers accompany the leaves in the fpring; but all their parts are imperfect; there is no pollen in the anthers, the fegments of the corolla are unnaturally long and narrow, of a greenifh fickly hue; and the germ is entirely abortive. Specimens were fent to Dr. Smith by Mr. Salmon, from a meadow near the Devizes, Wilts. We are in poffeffion of fpecimens gathered in the neighbourhood of York by the Rev. Mr. Wellbeloved. A native

A native of many parts of Europe, abundant in the weft and north of England, moft frequently, but by no means exclufively, in a calcareous foil. The whole plant has a ftrong and naufeous fmell. The recent fucculent bulb has an acrid, cauftic, bitter tafte, and is poifonous to man and other animals. A preparation of it is ufed in France, by order of government, to deftroy wolves. Deprived of its juices by age, or dried in an earlier ftate, it lofes its active qualities, and may be eaten with impunity. If taken out of the ground before the plants flower, and completely freed from its juices, it affords, like many other bulbs and tubers, a farinaceous matter which is wholefome and nutritious. Baron Stoerk of Vienna firft introduced it into ufe as a medicine. He fliced an ounce of the frefh root, and digefted it for forty-eight hours in a pound of vinegar, with a gentle heat. He then ftrained the vinegar, and added to it twice its weight of honey. The oxymel, thus produced, taken twice a day in dofes of a dram, and gradually increafed to an ounce or more, proved a very powerful diuretic, and in many cafes cured dropfies, which had been efteemed defperate. Pills are alfo made of the dried root reduced to powder, which have been found beneficial in removing obftructions. It is a favourite medicine in Germany and France; but the Englifh phyficians have found it a lefs efficacious diuretic than the fquill, by which it is ftill more excelled as an expectorant. The London college directs an oxymel colchici; that of Edinburgh, a fyrup; the latter differs from the former only in ufing fugar inftead of honey. The expreffed juice of the leaves, or an infufion of them in boiling water, applied as a lotion, has been ufed in France to deftroy the lice which infeft horned cattle. In an agricultural point of view, it is certainly a noxious weed to the farmer; not, indeed, on account of its poifonous qualities, for neither cows, horfes, nor fheep will touch it; but on account of its broad leaves, which occupy the place of better herbage. The only method of getting rid of it is to dig up the bulbs with a fpade, and to replace the earth when they have been feparated from it. 2. C. *montanum.* Linn. Sp. Pl. 2. Mart. 2. Lam. 2. Willd. 2. Hall. Helv. n. 1256. Allion. Ped. tab. 74. fig. 2. (C. montanum anguftifolium; Bauh. Pin. 68.) "Leaves linear, fpreading widely." *Root* fmaller than that of the preceding fpecies, with a darker coat. *Leaves* about three inches long, and half an inch broad, coming out with the flower in Auguft and September, and continuing green all the winter, at firft broadifh and egg-fhaped, afterwards almoft linear. *Flowers* reddifh purple, marked with lines; border deeply divided into narrow, almoft linear fegments. A native of Spain, Portugal, Italy, Switzerland, and the fouth of France; cultivated in England in 1629. 3. C. *variegatum.* Linn. Sp. 3. Mart. 3. Lam. 3. Willd. 3. Morif. tab. 3. fig. 4. "Leaves undulated, fpreading." *Leaves* appearing after the flowers are over, fmaller than thofe of C. autumnale, moft commonly three in number, of a paler and frefher green colour, lying clofe upon the ground, broad at the bottom, a little pointed at the end. *Flowers* whitifh, beautifully marked with purplifh fpots; border broad, with expanding fegments. A native of the iflands in the Archipelago, flowering in October or November.

Propagation and Culture. All the three fpecies are defirable ornaments to the flower-garden, particularly as they appear at a feafon when moft other plants have loft their beauty. Their bulbs require the fame treatment as thofe of the tulip. They fhould be taken up about the end of May, when the leaves are withered, and may be kept above ground until the beginning of Auguft. The third fpecies is rather tender. Many varieties of the common fort were known in the time of Parkinfon, and are ftill propagated by the florift; thofe moft common are the fingle and double-flowered white, the fingle and double-flowered purple, the variegated purple, the rofe-coloured, and the ftripe-leaved.

COLCHICUM *vernum hifpanicum;* Bauh. Pin. See BULBOCODIUM.

COLCHIS, or COLCHOS, in *Ancient Geography,* now *Mingrelia,* was bounded on the eaft by Iberia and Caucafus, on the weft by the Euxine fea, on the fouth by Armenia and part of Pontus, and on the north by mount Caucafus, dividing it from Sarmatia Afiatica. The moft noted cities in this country were Pityus, Diofcurias, Aea, and Cyta, which fee refpectively. The cities of Saracæ, Zudris, Surium, Madia, and Zaliffa, are alfo mentioned by Pliny, Strabo, and Ptolemy. Colchis was watered by many rivers, as the Corax, the Hippus, the Cyaneus, the Chariftus, the Phafis, the Abfarus, the Ciffa, and the Ophis, all emptying themfelves into the Euxine fea. The Colchians were, according to Herodotus, originally Egyptians; Sefoftris having left part of the army, with which he invaded Scythia, in Colchis, to people that country, and guard the paffes. Apollonius, Diodorus Siculus, Strabo, Euftathius, and Marcellinus, agree with Herodotus, who mentions many particulars in which the Colchians refembled the Egyptians. "They had," he fays, (lib. ii. c. 104, 105.) "the like tendency to woolly hair, and were of the fame dark complexion. There was a great fimilitude in their manufactures, particularly in their linen; for they abounded in flax, which they wrought up to a high perfection after the Egyptian method. In fhort, their whole way of life, and their language, had a great refemblance." Hence we may perceive, fays Bryant, (Anal. Anc. Myth. vol. iii. p. 451.) that though they were not, as the ancient hiftorian fuppofes, of the real Mizraim race, yet they came from a collateral branch, and were a colony from Egypt. Accordingly, this learned writer fuppofes, that the Colchians were one of the moft ancient colonies of the Cuthites, which is faid to have exifted many ages before the era of the Argonautæ; fo that, according to the poet (Apollonius Argon. l. iv. v. 267. v. 276.) many of the conftellations were not found in the heavens at the time when this colony was founded. One of the principal cities was called Cuta and Cutaia; and the country was called Cuteis and Cutais, from the Cuthite inhabitants. They retained, fays Bryant, a great reverence for the memory of their anceftor Chus, and the ridge of mountains, which ran through their country, was from him denominated Caucafus. The Colchians not only derived their origin from Egypt, but they were, as Bryant maintains, a part of that body, who by the Egyptians were ftyled the Hellenic and Phœnician fhepherds. They quitted Egypt, and were fucceeded by the Ifraelites, called afterwards the Jews. To this purpofe Diodorus fays, (lib. ii.), "that the Colchic nation upon the Pontus Euxinus, as well as that of the Jews, who fettled (in Canaan) between Syria and Arabia, were both founded by people, who went forth in early times from Egypt." As they enriched this country with many ufeful arts, it may well be expected that they fhould retain to the laft fome of their original excellence. We accordingly find, that writers extoll their advances in fcience, though it muft have been much impaired, before the Grecians were acquainted with their coaft.

In procefs of time many other nations fettled in Colchis, as the Heniochi, the Amprentæ, the Lazi, the Ligures, the Marfi, the Iftri, the Mofchi, and the Manralæ. The Colchians carried on for a long time an extenfive commerce. Strabo (lib. xi.) has given us a good defcription of their country;

country; and we may presume that the nature of it must have been always much the same. He says, that the whole region abounded with fruit of every kind, and with every material that was requisite for navigation. The only product of the country that was at all exceptionable was the honey, which had a bitter taste. They had plenty of timber, and many rivers for its conveyance downwards. They had also abundance of flax and hemp; together with wax and pitch. The linen manufactured by the natives was in high repute. Some of it was curiously painted with figures of animals and flowers; and afterwards dyed, like the linen of the Indians. And Herodotus tells us (lib. i. c. 203.), that the whole was so deeply tinctured, that no washing could efface the colours. They accordingly exported it to various marts, as it was every where greatly sought after. Strabo says, that many people who thought that they perceived a similitude between the natives of Colchis and those of Egypt, particularly in their customs, made use of this circumstance to prove the resemblance. He adds, that the high reputation and splendour, which they once maintained, may be known by the repeated evidences that writers have transmitted concerning them. The enterprising disposition or extensive commerce of the Colchians led them to establish many settlements; so that the coast of the Euxine, upon which they lived, was in many places peopled from them. One of their chief colonies seems to have been that of the *Amazons*, which see. Colchis, besides its other productions, was enriched with many mines of gold, which gave occasion to the fable of the golden fleece, and the *Argonautic* expedition, so much celebrated by the ancients. See ARGONAUTIC.

The Colchians were governed by their own kings in the earliest ages; for Pliny tells us (l. xxxiii. c. 3.) that Sesostris, king of Egypt, was overcome, and put to flight, by the king of Colchis. Little, however, that is certain, is known concerning their kings.

Upon the death of Œetes, in whose reign the famous expedition of the Argonauts occurred, Colchis, as we learn from Strabo, (l. i. and xvi.) was divided into several petty kingdoms; but the occasion of this division is not known. We find no further mention of the affairs of Colchis, or of the princes who reigned there, till the time of Xenophon, who tells us (Anab. l. v.) that the son of Œetes, the second of that name, reigned in Colchis, while he was making war in Asia. Colchis was afterwards subdued by Mithridates the Great, but revolted from him while his forces were employed against the Romans. As soon as the king of Pontus had concluded a peace with Sylla, he marched against the Colchians, who offered to submit, upon condition that he would appoint his son to reign over them, with the title of king of Colchis. This proposal so provoked Mithridates, that he caused his son to be arrested and loaded with chains of gold, sacrificing him soon after to his jealousy and ambition. Mithridates, finding that the Colchians obstinately refused to submit on any terms, assembled his troops in order to reduce them by force; but as he passed through the country of the Achæans, that people attacked him with such vigour, and defended the passes with such resolution, that, after having lost a great part of his army by the ambuscades of the enemy, and by the excessive cold of the country, he was under a necessity of returning into Pontus. Colchis, during its subjection to Mithridates, was governed by prefects of his appointment, one of whom was Moaphernes, great uncle to Strabo the geographer. The Colchians took part with Mithridates against Pompey; and, during that war, were governed by their own king, called Olthaus, who was vanquished, taken prisoner, and led in triumph by Pompey. Pompey conferred the sovereignty on Aristarchus, for his eminent services during the Mithridatic war. Afterwards Pharnaces II., king of Pontus, seized on the kingdom of Colchis, while Cæsar was entertained by Cleopatra in Egypt; but was soon obliged to abandon his conquests, and retire into the country of the Bosporani, where he was killed by Asander. From this time no mention of the Colchians occurs till the reign of the emperor Trajan, to whom they submitted of their own accord. Perhaps they were governed by their own king; for Strabo makes the river Phasis the northern boundary of the Roman empire. Under the emperors, Colchis was subject to the prætors who governed Bithynia and Pontus; but never made part of any province. Anc. Un. Hist. vol. ix. For the present state of Colchis or Colchos, see MINGRELIA.

COLCOTHAR, in *Natural History*, &c. The Latin writers of the middle ages use *colcothar* as a name of vitriol in general, which was called by the Greeks *chalcanthum*.

Colcothar is originally an Arabic word, which does not signify the common vitriol, but the *chalcitis*. The word has been spelt *calchuthar*, and from this the word *chalcitis* differs not very much. The Greeks of the middle ages followed the Arabians in the use of the word *colcothar*, but added to it a termination proper to their language, and particularly to the custom of those times, which seemed not to express exactly the same thing, but a diminutive of it: they wrote it *colcotharion*, or *chalcitarion*. This they also called the *orchis*, *orchidion*, the *ladi eladion*, and so in a thousand other instances. Avicenna uses the word *zagi* to express this substance, but then he is by no means determinate in it, but makes it include the *misy*, *sory*, and *melanteria*, as well as the *chalcitis*; but distinguishing in another place the several kinds of *zagi*, he tells us, that one was the *chalcand*, which was green; a second the *chalcitis*, which was yellow; a third the *sory*, which was red. *Alzagiat* is a name also used by him to express all these kinds; and this word the interpreters generally render *atramenta*, inks. This is generally supposed to express their being all black substances, which is not the case; but it properly signifies, that they are all vitriolic fossils: *atramentum* being a name of vitriol, as a substance used in the making of ink.

There are two kinds of *colcothar*, *natural* and *factitious*.

COLCOTHAR, *Natural*, otherwise called *chalcitis*, is a red vitriol, brought from Germany; formed from the common green vitriol, calcined naturally by some subterraneous fire.

COLCOTHAR, *Artificial*, is a substance which remains after martial vitriol has been calcined, and distilled for a long time by an intense fire; and by that means reduced to the redness of blood.

Mr. Le Fevre proposes an easy method of making *colcothar of vitriol*: he mixes two parts of filings of iron with one of sulphur, and a little water. After the acid of the sulphur has dissolved the iron, he exposes the paste to the air, and it changes into *colcothar*. See Mem. of the A. D. S. an. 1730, H. 52.

To obtain this article the most inferior kind of copperas is employed; it is first placed in a tolerably regular manner about two inches thick, upon iron plates which cover the first half of the bottom of a stove or oven which is heated, and nearly evaporates the water of crystallization; beyond these plates in the same oven, which is built with the best fire bricks, after having undergone the evaporation upon the iron plates, on which the copperas is thrown, it is then submitted to a red heat; during which, as may be readily supposed, its loss is considerable, eight cwt. of copperas producing scarcely five cwt. of colcothar. In the last named process the evaporation is entirely effected, and the substance completely calcined; from this it is taken to a mill, where it is ground

and

and sifted into an impalpable powder of a strong red colour.

Colcothar, after calcination, retains some of its acid, and imbibes moisture from the air; but if it is washed in water, the remaining acid is discharged; it no longer attracts moisture, and becomes what is called the *sweet earth* of vitriol. Unwashed colcothar is an antiseptic, tonic, astringent, and corrosive, and is therefore applied externally to all putrid, sanious, and fungous ulcers. See VITRIOL.

Colcothar is a dark red brown oxyd of iron, the residue of the distillation of nitrous acid, from nitre and vitriol of iron. This is calcined, washed, and thoroughly levigated, and in that state is much employed by painters, and in polishing glass and steel. It is called by artists crocus, or crocus martis, from its colour.

COLD, in common language, denotes the sensation which is felt, or the effect which is produced, by the abstraction of heat; that is, heat and cold are opposite to each other, and the existence or increment of the one is equal to the want or decrement of the other; so that the same degree of temperature may be called hot or cold, according as it is compared with a colder or a hotter temperature. Thus the climate of Great Britain is a cold climate in comparison with that of the West India islands, and a hot climate in comparison with that of Siberia. If a man warms one of his hands near a fire, whilst he cools his other hand by means of ice; and if, afterwards, he plunges both his hands in a bason of water of the common temperature of the atmosphere; that water will feel cold to the hand that has been heated, and hot to the other hand.

From this it appears that cold is not any thing real, but merely a privation of heat; so that instead of saying that a body has been cooled to a certain degree, it may with equal truth and propriety be said, that the body has been deprived of heat to that certain degree. Notwithstanding the simplicity of this theory, and the conviction which seems to accompany it, philosophers have often entertained doubts concerning it; and they have endeavoured to inquire into the real state of the matter, by devising experiments capable of demonstrating whether the cause of heat was any thing real, and that of cold only a privation or diminution of the former; or, *vice versâ*, whether the cause of cold was any thing real, and that of heat a diminution of it; or, lastly, whether the production of heat and the production of cold were not owing to two distinct principles, or elements. On the supposition that the cause of one of those effects only is real, it is much more natural to suppose, that the cause of heat is the real principle or element; since its effects, *viz.* enlargement of the bulk of bodies, the separation of their parts, &c. are such as must be produced by the introduction of something real; and the abstraction of this principle may naturally produce the effects of cold, such as contraction of the bulk of bodies, agglutination, &c.; whereas it would be unnatural to suppose that a body contracts its bulk, or its parts come into closer contact, because something else has been introduced amongst them. With respect to the last supposition, *viz.* whether the effects of heat and those of cold be not owing to two distinct principles, few arguments, and the equivocal result of few experiments, have, at times, been adduced in support of it. But the general and prevailing opinion amongst philosophers is, that a single element, called *caloric*, produces heat or the effects of expanding bodies, separating their parts, &c. and that cold is only a relative expression; that is, meaning only the decrement of heat; so that real or absolute cold consists only in the total abstraction of caloric; and, that such a point, *viz.* the zero of heat may be determined, has been shewn by the experiments, the discoveries, and the calculations, of some late eminent philosophers, *viz.* Irvine, Black, Crawford, and others. We shall presently give a compendious account of the particulars relating to the determination of this remarkable point; this total privation of heat, below which cold can not increase, since heat can not decrease. But it will be necessary, previously to it, briefly to mention an experiment which at first sight seems to prove that cold is something real, and independent of heat.

Let two concave metallic reflectors, about 10 inches in diameter, or larger, be placed facing each other at about the distance of 15 feet; and suppose the focus of each to be 18 inches distant from the surface of the speculum. Call the focus of one reflector A, and that of the other B. In order to situate the reflectors exactly facing each other, place a lighted candle in the focus of one of them, then move the other, so that the reflected image of the candle in the focus of this other reflector appears, by trial (*viz.* by receiving it upon a piece of paper), to fall in the direction of the focus and centre of the first reflector. Now, if a piece of red hot iron, or a burning charcoal be held in the focus, A, of one of those reflectors; and the bulb of a thermometer be placed in the focus, B, of the other reflector, the mercury in the thermometer will be raised by the radiant heat of the iron which falls upon the first speculum in a diverging manner, is reflected from it in parallel lines to the other speculum; and lastly, is reflected from this in converging lines to its focus, B, where the thermometer is situated. And that this is actually the case may be easily proved; for if the surface of either reflector be covered; every thing else remaining unaltered, the effect will not take place, *viz.* the mercury in the thermometer will not be heated. If, instead of the red hot iron, a piece of ice be placed in the focus, A, the thermometer will be lowered in the focus, B. Cover the surface of either reflector, and the mercury will rise in the thermometer. Uncover the reflector, and the mercury will descend, and so on. The result of this experiment has been supposed to prove that cold is something real or positive; for it proceeds from the ice to the speculum, is reflected from this to the other speculum, and is lastly reflected from this other speculum to its focus, B, where it cools the thermometer. But the true cause of the phenomenon is, that the heat of the thermometer is reflected upon the ice, in the same manner as the heat of the red hot iron was reflected upon the thermometer; for in this last disposition of the apparatus with the ice and the thermometer, the latter is the hottest of the two bodies. If instead of the thermometer, a piece of burning charcoal be placed in the focus, B, no person will hesitate to say, that the heat of the charcoal is reflected upon the ice at A. And there is no reason whatever for asserting that the same thing does not take place, when the thermometer is in the focus B.

We may now proceed to explain the determination of the zero of heat. If a quantity of water, whose temperature is 100°, be mixed with an equal weight of mercury, whose temperature is 50°, the temperature of the mixture will be found to be 88°; consequently the water has lost 12° of heat, and the mercury has gained 38° of heat. But if the original temperature be reversed, *viz.* the water at 50° be mixed with an equal weight of mercury at 100°, the temperature of the mixture will be 62°; consequently, the water has gained 12° of heat and the mercury has lost 38°. Therefore it is evident that the same quantity of caloric which raises the temperature of water 12°, will raise that of an equal weight of mercury 38°; or, by the rule of proportion, the same quantity of caloric which raises the temperature of water 1°, will raise that of the same weight of mercury 3.16 degrees.

Hence

Hence it may be concluded that when water and mercury are of the ſame temperature, the water actually contains rather more than three times as much caloric as an equal weight of mercury. Or, by the rule of proportion, if the caloric of water be called 1, that of mercury, (always meaning of an equal weight and equal temperature) will be 0.31. And theſe are called the ſpecific calorics of water and of mercury. By the like means the ſpecific calorics of various other bodies have been determined, in relation to that of water, which is always called one, or unity. The ſpecific caloric of ice, which is different from that of water, has been found to be 0.9. This may be ſufficent to give an idea of what is meant by ſpecific caloric in this place; but, for a full account and explanation of the ſubject, ſee the articles CALORIC and HEAT.

It has alſo been found, that when equal weights of water and ice are at the temperature of 32°; the water contains 140° of caloric more than the ice, which 140° of caloric are neceſſary to keep it in a fluid ſtate; nor can the ice be converted into fluid water without communicating to it 140° of heat. Further, ſince the ſpecific calorics of water and of ice, are as 1 to 0.9, it is natural to ſuppoſe that when they are both at the temperature of 32°, their abſolute or entire quantities of calorics are in the ſame proportion; *viz.* as 1 to 0.9, and 140° is their difference, 140 being the number of degrees of latent caloric, which water at the temperature of 32° holds more than ice at the ſame temperature of 32°. Now from theſe data, the zero of heat is determined by the following algebraical reaſoning, according to Dr. Irvine's theorem. Put x for the unknown number of degrees of caloric from 32° down to zero, or to the whole privation of heat; then the whole caloric of ice, in the above mentioned circumſtances, is x; and the whole or abſolute caloric of water is $x+140$. But the abſolute caloric of ice is to that of water as 0.9 to 1; or as 9 to 10; therefore we have this analogy $x : x+140 :: 9 : 10$, which gives the equation $10x = 9x + 1260$. And by tranſpoſition we have $10x - 9x = 1260$; or, $x = 1260$. Therefore, the zero or total privation of heat ſtands at 1260 degrees below the freezing point, or rather the melting point of congealed water. The ſame zero of heat may be determined by means of other ſubſtances; and it has thus by various means been calculated by other philoſophers: but as their determinations do not agree, ſome fallacy has been generally ſuſpected either in the theory or in the operations. The following are the reſults of the experiments, and the calculations made by divers perſons for the determination of the zero of heat.

Fahrenheit's Scale: degrees below the 0 of that Scale.

Lavoiſier and Laplace, from experiments on a mixture of 9 parts of water, and 16 of quicklime, placed the zero of heat at - - -	$3458\frac{1}{4}$
Their experiments on a mixture of ſulphuric acid, and water in the proportion of 4 to 3, fix the zero of heat at - - - -	$7292\frac{1}{4}$
Their experiments on a mixture of the ſame fluids in the proportion of 4 to 5, place it at -	$2630\frac{1}{2}$
Their experiments on a mixture of nitrous acid and quicklime, fix the 0 of heat at - -	$23837\frac{3}{5}$
Seguin places the zero of heat at - -	$1894\frac{1}{2}$
Other experiments of the ſame fix it at -	2709
And from other experiments he is led to fix it at	$1662\frac{3}{4}$
Kirwan fixes it at - - -	1350
Crawford places it at - - -	1532
Gadolin's experiments fix it at - -	$1461\frac{3}{5}$

This immenſe diſagreement of reſults ſeems to indicate that ſome one at leaſt of Dr. Irvine's ſuppoſitions muſt be miſtaken. But the preſent Dr. Irvine in his edition of his father's eſſays, obſerves, that his father's method of computing the zero of heat or point of total privation, does not appear to lie under any fallacy; but that the great diſcordance between the determinations of that point, as calculated by different perſons, ariſes from the difficulty of determining with accuracy the proportion of the ſpecific calorics, or capacities of ice and water.

In the preſent ſtate of civil ſociety, the production of cold, as ſubſervient to the advantage, the conveniency, and the luxury of mankind, eſpecially under certain obvious circumſtances, and at certain places, is a matter of conſiderable conſequence. The artificial production of cold is by no means ſo eaſy as the production of heat; ſo that great attention muſt be paid to a variety of circumſtances, in order that the cooling of liquors, of apartments, &c. may be performed in the eaſieſt, and moſt economical manner poſſible. The various known artificial methods of cooling, are ventilation; the uſe of cold caves, wells, grottos, &c. when their temperature is lower than that of the ambient air; evaporation; the uſe of ice where ice is to be had; the ſolution of certain ſalts; and the expanſion of air; but for the particular details and practice of thoſe methods, ſee the articles CONGELATION, VENTILATION, FREEZING, EVAPORATION, and EXPANSION.

COLD, in regard to *its action on the living body*, may be conſidered, according to popular language, and the common feelings of men, from which that language is deduced, as a poſitive agent. In ſtrictneſs, it is merely a privative, or relative term, ſignifying a greater or leſſer abſtraction of heat, or *caloric*: but for practical purpoſes, it is uſeful to refer to the ſenſations, as a ſtandard, and to adopt the vulgar acceptation of the term.

The operation of cold on the animal body may be regarded in *three* points of view: 1ſt, as to its general effects, as well in thoſe degrees in which it is conſiſtent with the health and vigour of the body, as in thoſe in which it becomes deſtructive of the principle of life; 2dly, as to its influence in the production of different diſeaſes; and, 3dly, as to its remedial effects, or its power of alleviating and curing ſome of the moſt fatal diſorders, to which the animal economy is liable. In attending to the detail of facts, under the two firſt heads, we ſhall neceſſarily be led to conſider alſo the means of preventing and removing the pernicious effects of the agency of cold.

I. Of the *general effects* of cold on the living body. A certain quantity of heat is obviouſly indiſpenſible to the exiſtence of life, throughout both the animal and vegetable world. The returns of ſummer and winter alternately multiply and diminiſh to a great extent the number of living beings, eſpecially of thoſe which poſſeſs a comparatively leſs perfect organization; and, in all, a free circulation of the fluids is requiſite for the ſupport of the vital principle. Hence life is incompatible with that degree of cold, which produces a congelation of the fluids. It is a law in the nature of heat, as well in living as in dead matter, that it is communicated from a body poſſeſſing a larger quantity, to any other body which comes in contact with it, poſſeſſing a ſmaller quantity, until an equilibrium is produced, or until the degree of heat is the ſame in both. Were living bodies, therefore, poſſeſſed of no other properties, but thoſe which belong to them in common with inorganic bodies, in an atmoſphere of the temperature of 32° of Fahrenheit's thermometer (the freezing point of water), or a little lower, it is obvious that life muſt ceaſe. The animal body, however, is endowed with a power of generating or evolving heat, to a conſiderable extent, much above the ordinary temperature of of the atmofphere. This power is even increafed by the neceffity occafioned by external cold, and diminifhes with the increafe of the atmofpherical warmth; fo that, during a ftate of health, the temperature of the animal body is pretty uniformly the fame, notwithftanding the extenfive variations of the external temperature (within an indefinite limit). Or, in other words, there is in the body a power of regulating or varying the evolution of heat, according to the demand made from without. In the human body, the degree of heat is regularly about 98° of Fahrenheit's fcale; in birds, it is fomewhat higher; and in fome other animals it is much lower, efpecially in the amphibia, &c. which have hence been called cold-blooded animals, and which fuffer great variations of their heat.

In order to afcertain the truth or falfity of an affertion, that fome animals, efpecially ferpents and fifh, had recovered their vitality after being frozen, Mr. John Hunter inftituted a number of interefting experiments on the power of different animals in refifting the agency of cold. Carp was gradually deftroyed, and froze, when fubmitted to a freezing mixture at 10° Fahrenheit, and did not recover. It was with great difficulty that he fucceeded in freezing a dormoufe, fuch were its powers of evolving heat, and the non-conducting quality of its integuments; and it was not till the hair was wetted that life was deftroyed, and the animal, when dead, became ftiff, and could not be recovered. When a toad was fubmitted to a fimilar cold mixture, the water froze round the animal, but it did not die. In other cafes the heat was readily overcome.

It appeared from thofe experiments, that an animal muft be deprived of life before it can be frozen; and that the power of refifting the cold was in proportion to the perfection of the animal, and the natural heat proper to each fpecies and to each age. It may, perhaps, alfo depend in fome degree on other circumftances, not yet afcertained; as in fome of the experiments on dormice, it was found, that in thefe animals, which are of a conftitution to retain nearly the fame heat in all temperatures of the air, it required the greateft cold that could be produced to overcome this power; while in the toad and fnail, whofe natural heat is not always the fame, but is altered very materially according to the external heat or cold, this power was exhaufted in a degree of cold not exceeding 10° or 15°, and the fnail being the moft imperfect of the two, its powers of generating heat were by much the weakeft. But in all there was a great exertion or an expence of the animal powers in this refiftance, in proportion to the neceffity; and the whole animal life was thus, at length, exhaufted. Hence thofe animals, which cannot fupport life for any confiderable time, at the temperature of the freezing point, always endeavour to procure fuch places of abode in the winter as feldom arrive at that point. Thus we find toads burrowing, frogs living under large ftones, fnails protected under the fhelter of ftones and in holes, fifh having recourfe to deep water, all which places are generally above the freezing point in our hardeft frofts; however, our frofts are fometimes fo fevere as to kill many, whofe habitations are not very fecure. When the froft is more intenfe or of longer ftanding than common, or in countries where the winters are always fevere, there is generally fnow, and the water freezes; the advantages arifing from thefe two circumftances are great; the fnow ferving as a blanket to the earth, and the ice to the water. See Philofoph. Tranfactions, vols. lxv. and lxviii.

The power of refifting the action of cold, or of evolving heat, in greater quantity than the furrounding cold media abftract it, could not of courfe be determined by experiment on the human body; but many ordinary and accidental circumftances have demonftrated its exiftence to an extent, which could not have been anticipated. It is fcarcely neceffary to allude to the common occurrences of the winter feafon, when the heat of the body remains at its natural degree of 98, during an expofure to an atmofphere, of 10, 15, or 20 degrees or more below the freezing point, even in this country. In Ruffia, Mr. Tooke obferves, that the drivers and their horfes, during extreme cold, feel little or no inconvenience in purfuing their employment, along the roads, though the beards of the former, and the muzzles of the latter, are covered with hoar froft, and little icicles, from the congelation of their breath; and they travel all day, in the fevereft cold of that northern climate, without receiving any detriment. "Nay, even from twenty to twenty-four degrees" (below the zero or freezing point, we prefume) "of Reaumur, women will ftand rinfing the linen through holes in the ice, four, five, or fix hours together, often bare-foot, with their hands dipping in the water all the while, and their draggled petticoats ftiff with ice." Tooke's View of the Ruffian Empire, vol. i. Even the extremes of cold in Siberia, in the neighbourhood of Hudfon's bay, &c. are compatible with human life, aided by a cloathing of furs, and other flow conductors of heat. We have learnt from accidents, alfo, that cold is fometimes refifted, during a long expofure, without fuch aid. An interefting account is before the public of the cafe of Elizabeth Woodcock, who was involved in a fnow-drift, on February 2d, 1799, in her way home from market, where it is fuppofed fhe drank too freely of fpirituous liquor. The fnow accumulated over her to the height of about fix feet, a fort of hollow cone being left from her head to the furface, through which breathing was performed. From this fituation fhe was removed on the 10th of February, having lain eight days in the fnow. Her life was preferved; but the greater part of her feet were deftroyed. A hiftory, fomewhat refembling the foregoing, is detailed in the "Journal de Medecine" of Paris, for the year 1767, of a man who refifted the action of cold from fnow, in which he was buried four days, and from which he was removed alive on the fifth day; and of a crew of 14 men, fhipwrecked, and immerged in the fea during 23 hours, eleven refifted the action of the cold, and recovered. We fhall have occafion to mention thefe cafes more particularly in the fequel of this article.

Such, indeed, is the power of refiftance to external cold in the human body, or rather fuch the conftant evolution of heat, that an atmofphere of the temperature of 98° of Fahrenheit, which, of courfe, does not abftract any of the heat of the body, is extremely incommoding to the feelings. In a phyfical fenfe, every temperature of the air, or other furrounding medium, below 98°, might be denominated *cold;* but with regard to the feeling and to the health, a degree much lower, namely, from 60° to 65°, is the moft grateful and invigorating. The external medium at the temperature of about 62° appears to abftract the heat of the body, in the fame proportion in which it is generated, without any extraordinary exertions of the fyftem; and therefore neither contributes to exhauft its powers, nor to excite uneafy fenfations. Thus the conftitution of man is wifely adapted to the general or medium temperature of the habitable globe. Hence alfo the general denominations which are given to different degrees of temperature. In a degree of heat from 60° to 64°, every exertion of the body, which is neceffary to man's fubfiftence or gratification, is performed with eafe and fafety; and this degree is called *temperate.* The higher degrees up to 70° are called *warm,* and all above that *hot.* In the inferior range of the fcale, a few

few degrees below 60°, as down to 50° or 47°, are denominated *cool;* and all below, *cold.* There is, however, considerable difference among men, even in a ftate of health, in affigning names to particular degrees of the thermometric fcale; as their fenfations vary, according to the power, which their refpective conftitutions poffefs, of evolving heat. This depends much upon the original vigour of the fyftem, efpecially of the heart and arterial fyftem; it is alfo much influenced, as is every other function of the body, by habit. Mr. Tooke attributed much of the impunity, with which the Ruffians perform their labours, already mentioned, during extreme cold, to their "being feafoned to it;"—a popular term, which implies the acknowledged effect of habit on thofe who take their refidence in climates of widely different temperature.

To perfons who, from vigour of conftitution, or from habit, readily evolve a confiderable quantity of heat, efpecially during moderate corporeal exercife, a degree of cold, which, to the weak and unhabituated, is a fource of painful fenfations of chillinefs, is agreeable to the feelings, and conducive to health. For the fenfation of cold is merely relative; it is in proportion to the previous fenfation of heat, and to the power of evolving it, to fupply the place of that which the external cold medium abftracts. Hence the fame temperature, at different times, excites even oppofite fenfations, according to the ftate of the circulation from exercife, or from difeafe, or previous expofure, &c. And thofe oppofite fenfations are even excited at the fame time in different parts of the body, as is familiarly illuftrated by the following experiment. If the hands be immerfed in two veffels of water, the right hand into a veffel containing water at the temperature of 80°, for inftance, and the left into a veffel in which the water is of the temperature of 40°, and after remaining a fhort time, both be immerfed into a veffel which contains water at the temperature of 60°; this water, of the intermediate degree of heat, will excite a fenfation of cold to the hand, which had previoufly been expofed to the temperature of 80°, and will feel warm to that which had been immerfed in the water of 40°. During the previous immerfion, for a fhort time, a greater abftraction and evolution of caloric had been made in the left hand, under a temperature of 40°, and a leffer in the right, under the higher temperature of 80°; and hence, when the abftraction is fuddenly diminifhed in the left hand, by a higher temperature of 60°, and fuddenly increafed in the right, by the lower temperature of 60°, the fenfation is the fame as if heat were actually added to the left, and cold applied to the right hand; for the fenfation is, as we before ftated, relative.

At the temperature of 62° of Fahrenheit's fcale, the balance of the evolution and abftraction of heat is fteadily maintained, without exertion or injury to the human body; but very low temperatures, by abftracting the animal heat more fpeedily than it can with eafe be evolved, exhauft the living powers, and ultimately deftroy the principle of life.

The firft effect of cold, applied to the human body, is to weaken and diminifh the action of the blood-veffels, efpecially of the fuperficial branches of the arteries, which become unable to tranfmit the blood in the ufual quantity through the integuments; and more efpecially in the extreme parts, as the hands and feet, which are at the greateft diftance from the heart; and in projecting parts, as in the ears, nofe, fcrotum, &c. which expofe a larger furface to the cold. Hence the fkin becomes pale, and, contracting round the miliary glands and roots of the hairs, exhibits a roughnefs, which is compared to the fkin of an unfeathered goofe, and is technically termed, *cutis anferina.* By the fame contraction of the fmaller veffels, and the diminifhed circulation, the extreme and projecting parts are diminifhed in fize; thus rings, which are tight on the fingers, while the body is warm, drop off in cold weather; and even the fhoes fall from the feet during extreme expofure. The heart, and the whole arterial fyftem, become weak, and the number and ftrength of their pulfations are diminifhed, according to the obfervations of Dr. Currie and Dr. Rufh. Dr. Currie remarks, that the natural pulfe of one of the men, on whom his experiments in the cold bath were made, was about 70 in a minute; but that, in confequence of agitation of mind, it was never flower than 85 before immerfion, and generally more. However this might be, it funk invariably to 65 in the water, became firm, regular, and fmall. After being in the bath fome time, it could hardly be felt at the wrift. Phil. Tranfactions, vol. lxxxii. But, from a feries of experiments, made by Dr. Stock of Briftol, a refult fomewhat different was obtained. The ftrength of the arterial action was, in all cafes, diminifhed by immerfion in cold water, but its frequency was, with fcarcely any exception, increafed: in many cafes, from the combination of extreme weaknefs and rapidity, it was fcarcely poffible to count the number of pulfations. The circumftance of the frequency of the pulfe increafing with its debility, feems to be more analogous to the general obfervation with refpect to arterial action. This fact alfo agrees with the obfervations made by Drs. Spooner and M'Donnell, at Edinburgh. See "Stock Medical Collections on the Effects of Cold," *appendix.* Spooner "Diff. Inaug. de Afcite Abdom." Edin. 1785. From the debility of the arterial fyftem, the blood is partially delayed in its courfe through fome of the cutaneous veffels, and, not undergoing the change of colour, which a circulation through the lungs produces, it gives a blueifh or livid colour to the fingers, ears, and other projecting parts. If the cold is intenfe, or the expofure continued long, the circulation in thefe parts becomes altogether interrupted, and the power of evolving heat being altogether deftroyed, a partial lofs of the vital principle takes place, or, in other words, mortification enfues, and the parts fall off from the body. The portions thus deftroyed, are ufually faid to be *froftnipped,* of which an example has already been mentioned, in the cafe of Elizabeth Woodcock, who loft her feet from this caufe. But inftances of this are fo numerous, that it will be unneceffary to detail them here.

The influence of cold in debilitating the force of the circulation of blood is alfo evinced in the perfons of the inhabitants of the frigid zone. "As we approach nearer to the north pole," Mr. Tooke has remarked, "both the animal and vegetable productions of nature become more and more ftunted. The ordinary ftature of the Samoyedes feldom exceeds four or five feet, and their whole exterior correfponds with their dwarfifh fize. The fame bodily ftructure, and the fame features of face, are applicable to the Eaft Siberian tribes. The Kamtfhadales are equally dwarfifh." View of Ruffia, vol. 2d. It is remarked by Linnæus, that the hares, partridges, and other animals, which inhabit the northern climes, are confiderably fmaller in fize, than the fame fpecies in more fouthern countries. Amœnitates Academicæ, vol. vii.

From the languor and weaknefs of the arterial fyftem, produced by the application of cold, other effects on the conftitution neceffarily accrue. It is a fact, well eftablifhed in phyfiology, that a free circulation of blood, which has undergone the falutary change produced by refpiration, to the brain and nervous fyftem, is requifite for the fupport of the fenfibility. If the circulation is fufpended for a few moments, as in fyncope, the fenfibility of the frame is alfo fufpended; and, on the other hand, where there is a more

more than ordinary fupply of blood to any part, as in inflammation, the fenfibility is highly augmented. Hence another immediate effect of the agency of cold on the human body, is a diminution of the fenfibility of the parts on which it is exerted. This is univerfally felt in the numbnefs of the hands and fingers, which, under the impreffion of cold, are altogether incapable of accurate difcrimination of touch; the whole of the furface of the fkin partakes of the imperfect feeling. The tongue is alfo incapable of diftinguifhing the peculiar flavour of fapid bodies, if they be extremely cold; and the fenfe of fmell is in a confiderable degree enfeebled by cold. If the cold be intenfe, or its application long continued, the powers of the whole nervous fyftem become weakened; a torpor of the animal functions enfues; the action of the mufcles is feeble, and fcarcely obedient to the will; an unconquerable languor and indifpofition to motion fucceeds; a gradual exhauftion of the nervous power fhews itfelf in drowfinefs, which terminates in fleep, from which the perfon, unlefs fpeedily roufed, frequently awakes no more.

A ftriking illuftration of thefe effects of cold is related by captain Cook, in an occurrence which took place during a botanical excurfion of fir Jofeph Banks and Dr. Solander, among the hills of Terra del Fuego. The party, confifting of 11 perfons, were overtaken by darknefs, and obliged to fpend the night on the hills, during extreme cold. Dr. Solander, who had more than once croffed the mountains which divide Sweden from Norway, well knew that extreme cold, efpecially when joined with fatigue, produces a torpor and fleepinefs that are almoft irrefiftible; he, therefore, conjured the company to keep moving, whatever pains it might coft them, and whatever relief they might be promifed by an inclination to reft; "whoever fits down," faid he, "will fleep; and whoever fleeps will wake no more." Thus at once admonifhed and alarmed, they fet forward; but while they were ftill upon the naked rock, and before they had got among the bufhes, the cold became fuddenly fo intenfe, as to produce the effects that had been moft dreaded. Dr. Solander himfelf was the firft who found the inclination, againft which he had warned others, irrefiftible, and infifted upon being fuffered to lie down. Mr. Banks entreated and remonftrated in vain; down he lay upon the ground, though it was covered with fnow; and it was with great difficulty that his friend kept him from fleeping. Richmond alfo, one of the black fervants, began to linger, having fuffered from the cold in the fame manner as the doctor. Mr. Banks, therefore, fent five of the company forward, to get a fire ready at the firft convenient place they could find, and himfelf, with four others, remained with the doctor and Richmond, whom, partly by perfuafion and entreaty, and partly by force, they brought on; but when they had got through the greater part of the birch and fwamp, they both declared they could go no farther. Mr. Banks had recourfe again to entreaty and expoftulation, but they produced no effect. When Richmond was told, that if he did not go on he would in a fhort time be frozen to death, he anfwered, that he defired nothing but to lie down and die. The doctor did not fo explicitly renounce his life; he faid he was willing to go on, but that he muft firft take fome fleep, though he had before told the company that to fleep was to perifh. Mr. Banks and the reft found it impoffible to carry them, and there being no remedy, they were both fuffered to fit down, being partly fupported by the bufhes, and in a few minutes they fell into a profound fleep. Soon after fome of the people who had been fent forward, returned with the welcome news, that a fire was kindled about a quarter of a mile farther on the way. Mr. Banks then endeavoured to wake Dr. Solander, and happily fucceeded; but though he had not flept five minutes, he had almoft loft the ufe of his limbs, and the mufcles were fo fhrunk, that his fhoes fell from his feet; he confented to go forward, with fuch affiftance as could be given him; but no attempts to relieve poor Richmond were fuccefsful. He, together with another black, left with him, died. Several others began to lofe their fenfibility, having been expofed to the cold and the fnow near an hour and a half, but the fire recovered them. See captain Cook's firft Voyage.

In addition to this interefting narrative, many examples of death from extreme cold, occurring in a fimilar way, are recorded. Bomare obferves that travellers among the Glaciers of Switzerland, are fometimes furprized and killed by the cold, efpecially thofe who travel on horfeback; and that the approaching danger manifefts itfelf by a ftrong difpofition to fleep; fo that if the perfon does not immediately refift it, and put himfelf into a brifk movement, death is inevitable. Dictionaire d' Hift. Naturelle, *Art.* Froid. Sauffure alfo has remarked that among thefe mountains, even in the fineft weather of fummer, fudden ftorms of the moft intenfe cold wind, with fnow that obfcures the air, are not uncommon, and are frequently fatal to the traveller; for he perifhes with cold, if he ftops; and if he goes on at hazard, he falls in all probability over a precipice. Voyage dans les Alpes, tom. ii.

The French peafants, who inhabit the feet of the bleak mountains, which feparate France from Spain, annually fuffer fatal accidents, in their journeys acrofs the perpetual fnows, which cover them. In February 1765, five men who were returning from the Spanifh forges, to bring their families the fruits of their labour, were caught in one of thofe ftorms defcribed by Sauffure. One of them, named Boutillât, feized by the cold, immediately felt extreme laffitude, his limbs were unable to fupport him, and he fell down, overcome with fleep, and was foon overwhelmed with the fnow. The cold continued, and he lay four days, infenfible, in the fnow, which, to ufe the words of Mr. Hunter, probably "ferved as a blanket," to fhelter him from the more intenfe cold of the atmofphere. He awoke on the 5th morning, with a fenfation of burning thirft in his throat, and he inftinctively bit of the fnow, in which he was enveloped. A fimilar hollow cone, through which he had breathed, was found in this inftance, as in that of Elizabeth Woodcock before defcribed; and he was, like her, unable to affift himfelf to throw off his cold covering. But fome men, fent in fearch of him by the magiftrates of the village, fortunately difcovered him. The cuticle of a confiderable part of his body was detached, as if by blifters; but he was not fenfible of pain; in feveral places gangrene had occurred. When he was taken home, the limbs were ignorantly wrapped in warm linen, fome of which was dipped in aromatic liquors. The feet were deftroyed by the mortification, and came off; and in twelve or fourteen days after the accident he died. M. Pilkes, who details the hiftory of the cafe, remarks, that, if cold applications had been made, inftead of the warm linen, and aromatic liquors, his life might probably have been preferved. See Journal de Medecine, Paris, 1767, tom. xxvii.

The effect of extreme and continued cold is not only to deftroy animal life, but alfo to preferve animal fubftances from decompofition by the procefs of putrefaction. Hence in regions of unvarying cold, the bodies of thofe who perifh are preferved entire under the fnow. Bomare affirms, that there are ftill found in South America, a confiderable number of the firft conquerors of the new world, who, at the commencement of the fixteenth century, preferred to a long and circuitous route, the ſhort but dangerous paſſage of the mountains of Peru, in order to examine more ſpeedily the rich mines, which had been deſcribed to them. "The warmth of their avarice, and their ardour in ſearch of gold, could not defend them from the influence of cold, from which they periſhed, and by which they are ſtill preſerved, with all that they carried with them, and in the various attitudes, in which they were frozen and ſurpriſed by death, conſtituting a ſort of natural mummies." Dict. d' Hiſt. Nat. And Bartholin obſerves, that the Daniſh ſailors had informed him, that bodies had been preſerved in Spitzbergen during 30 years. Gazette de Salut.

When cold is combined with *moiſture*, even at a much higher temperature, its effects are extremely deleterious, and even fatal, independent of the train of diſeaſes, which it excites, and which we ſhall deſcribe hereafter. For water not only conducts the heat away more rapidly, but, by evaporating, it abſtracts an additional quantity from the body, eſpecially when it is expoſed to wind: in this caſe, a new ſheet of cold water is, as it were, perpetually applied to the ſurface of the body, which induces an extreme chill, both by the number of particles in contact with the ſkin, and their greater facility of receiving heat. It appears, however, that the deleterious effects of cold combined with moiſture, are ſomewhat different from thoſe which are the conſequence of a dry cold; and that cold *ſalt* water is leſs prejudicial to the body, than cold *freſh* water; as the following facts and experiments, related by Dr. Currie, will evince.

On the 13th of December, 1790, an American ſhip was caſt away on a ſand bank, that lies in the opening of the river Merſey, into the Iriſh channel. The crew got on a part of the wreck, where they paſſed the night; and a ſignal which they made being diſcovered next day from Hillberry iſland, a boat went off, though at a great riſk, and took up the ſurvivors. The unfortunate men had remained twenty-three hours on the wreck; and of fourteen, the original number, eleven were ſtill alive, all of whom in the end recovered. Of the three that periſhed, one was the maſter of the veſſel; another was a paſſenger, who had been a maſter, but had loſt or ſold his ſhip in America; the third was the cook, who was a weakly man; he died only a few hours before the boat reached the wreck. The two maſters had been long dead. This fact excited much curioſity, and their death was attributed to intoxication from a free uſe of cherries from a keg, which had contained cherry-brandy. But in fact nothing was preſerved, neither food nor drink, and the whole crew were upon an equality, except that ſome were deeper in the water than others; and the two maſters had the advantage in this reſpect, for they ſat on the only part of the wreck that was out of the ſea; they were, however, frequently overwhelmed by the ſurge, and at other times expoſed to heavy ſhowers of ſleet and ſnow, and to a high and piercing wind. The temperature of the air, as nearly as can be gueſſed, was from 30° to 33° of Fahr. and that of the ſea, from trials in ſimilar circumſtances, from 38° to 40°. The mate was generally up to the middle in the water. The crew were worſe ſituated, being ſome of them up to the ſhoulders. They were not at any time able to change their poſition, but kept their legs in pretty conſtant motion to counteract the cold, their arms being employed in holding the wreck. It is remarkable that a poor negro, who eſcaped almoſt unhurt, was perhaps deepeſt in the ſea of any.

The maſter of the ſhip, Capt. Scott, a native of North Carolina, and about 40 years of age, died firſt. As they were in the dark, Mr. Amyat, the mate, could not ſee his countenance; but he was firſt alarmed by hearing him talk incoherently, like one in the delirium of fever. By degrees his voice dwindled into a mutter, and his hearing ſeemed to fail. At length he raiſed himſelf up in a ſort of convulſive motion, in which he continued a few ſeconds, and then fell back dead on the deck. This happened about eight o'clock in the evening, four hours after the ſhip went aground. Soon after this, Capt. Daviſon, who was about 28, began to talk incoherently, in the ſame manner as the other; he ſtruggled longer, but died in the ſame way about eleven at night. The cook died in the forenoon of the ſucceeding day; he was a low-ſpirited man, and deſponded from the beginning. All the reſt held out, though ſorely pinched with cold and hunger, till they were taken up about three in the afternoon. Mr. Amyat ſaid that his hands and feet were ſwelled and numb, though not abſolutely ſenſeleſs; he felt a tightneſs at the pit of his ſtomach, and his mouth and lips were parched; but what diſtreſſed him moſt were cramps in the muſcles of his ſides and hips, which were drawn into knots. Though immerſed in the ſea, they were all of them very thirſty; and though expoſed to ſuch ſevere cold, not one of them was drowzy, nor did ſleep precede death in thoſe who periſhed.

Reflecting on the curious facts mentioned in this melancholy narrative, Dr. Currie was led to inſtitute a ſeries of comparative experiments on the effects of immerſion in cold freſh water and ſalt water baths on the human body. The reſults tended to elucidate in ſome meaſure the facts in queſtion; as well as to aſcertain ſome important practical deductions, which may be of uſe to perſons ſuffering under ſimilar accidents; and others, which relate to the general uſe of the cold-bath. Dr. Currie imagined that the death of the two maſters was to be imputed to their poſition on the wreck. Being expoſed to heavy ſhowers of ſleet and ſnow, they might ſuffer from being wet with freſh, rather than ſalt water; the chilling effects of evaporation might operate againſt them, promoted as they muſt have been by the high wind; or they might receive injury from their frequent immerſions in the ſea, producing an *alteration* in the media ſurrounding. The experiments of Dr. Currie ſeem very ſtrongly to corroborate theſe ſuppoſitions.

The immediate effect of plunging into a cold *ſalt water* bath, was a reduction of the temperature of the body, from its natural ſtandard 98° to about 87°; but while the perſon remained in the water, the conſtitution was called on for a greater evolution of heat, and his temperature aroſe gradually to 94° or 95° in the courſe of twelve or fifteen minutes. On emerging, and being expoſed to a north eaſt wind, the temperature again rapidly ſunk, even while attendants were rubbing him with towels, to 87° or 88°. But a warm bath ſoon reſtored the natural heat. After immerſion in a *freſh water* bath, the heat of the body ſunk gradually, and not ſo low; but after being 30 minutes in it, even the hot bath with difficulty reſtored the heat. In two minutes after the perſon, who had been in the freſh water bath, was put into a warm bath at 90°, he fell into a violent ſhiver, and his heat fell two degrees. The bath was then heated to 95° and 96°, but ſtill he felt cold. It was heated to 99°: he continued in it five minutes, and his heat was ſtill one degree lower, than when he quitted the cold bath. The heat was gradually raiſed to 106°, when the ſenſe of coldneſs of which he had complained at the pit of the ſtomach, gradually went off. After immerſion in the cold ſalt water bath, the perſon, who was the ſubject of the experiment, had been uſually kept in the warm bath till his natural heat was nearly recovered; but now after being half an hour in the heat of 106°, his own heat was ſtill 93°. He now became ſick and very languid, a cold ſweat covering his face, his pulſe very quick and feeble. He was removed into bed, but paſſed a feveriſh

feverish night, and next day had wandering pains over his body, with great debility, resembling the beginning stage of a fever. By cordials and rest, this went off. See the experiments related in the Philos. Transactions, vol. lxxxii. for 1792, and the Appendix to Dr. Currie's Medical Reports on the effects of water, &c. vol. i.

The facts just stated clearly point out the greater danger of being wet with *fresh* than with *salt* water: the superior safety of the latter, probably, consists in the stimulus of the saline impregnation upon the skin, which may counteract the debilitating effects of the cold. The practical inferences which Dr. Currie deduced from these facts are extremely important. He observes,

"1. It is, I think, already well known among seamen, that where there is only the choice of being wet with salt or fresh water, it is always safest to prefer the first. In the heavy showers of rain, hail, or snow, by which gales of wind are generally accompanied, the men that must be exposed to them, ought, like Lieutenant Bligh and his crew, to wring their clothes out of salt water.

"2. In all cases where men are reduced to such distress by shipwreck, or otherwise, that they have it only in their power to chuse between keeping the limbs constantly immerged in the sea, or exposing them to the air while it rains or snows, or of being exposed to it, where the sea is at times washing over them, it is safest to prefer a constant immersion; because, in the northern regions, where the cold becomes dangerous to life, the sea is almost always warmer than the air, as the experiments of Sir Charles Douglas show; and because there is not only a danger from the increased cold produced by evaporation, but also from the loss of heat by the rapid changes of the surrounding medium, as the foregoing experiments point out.

"3. Whether, in high and cold winds without rain or snow, and where a situation may be chosen beyond the reach of the waves, it is safer to continue in the air, or to seek refuge in the sea, must depend upon several circumstances, and cannot perhaps be certainly determined. The motives for chusing the sea will be stronger in proportion as the wind is high and cold, and in proportion as the shore is cold."

Some deductions also were obtained from the experiments, which relate to the common use of the cold-bath, and which, as they do not exactly accord with the vulgar opinion on this subject, and may contribute to correct some practical errors in the use of the bath, we shall transcribe.

"The air and the water being equally cold, and both 45° or under, I found the loss of heat in passing from the one to the other, to be regulated in the following way.

"1. If, instead of being exposed naked to the wind, previous to immersion in the water, the body was kept warm by a flannel covering, the mercury fell much less on the first plunge.

"2. If, after plunging in the water, the person continued in it only a minute or two, a subsequent fall of the mercury did not always take place on his emerging into the air. On the contrary, there was sometimes a rise on such occasions in the mercury, especially if the atmosphere was at rest.

"3. In one instance, after continuing in the water fifteen minutes, on rising into the air in a perfect calm, though during a frost, there was little or no seeming diminution of the heat; while exposure under similar circumstances, with a north-east wind blowing sharply, though the air was many degrees warmer, produced a rapid diminution. The effects of the wind in diminishing the human heat are indeed striking, and are not, in my opinion, explained by the common supposition."

Hence we see an obvious necessity, that invalids should not allow themselves to become chilled, before going into the cold-bath, that they should leave it speedily, and not suffer any exposure to a cool wind on emerging; since by such means they not only counteract the beneficial effects of bathing, but even incur considerable danger. See BATH and BATHING.

Hitherto we have attended to the effects of extreme cold, with or without the joint operation of moisture, on the human body, in a state of previous natural temperature. The action of cold in more moderate degrees on the body, heated to a preternatural extent, by exercise, or other causes, affords a subject of not less important consideration: The more important indeed, as the popular notions on this topic are mostly founded in error, and lead to daily practical consequences of very pernicious tendency. So many instances of the noxious effects of exposure to cold, or of drinking cold liquids, when the body was hot, are recorded, and are believed frequently to occur, that a conviction of the fact is universal; and this conviction is corroborated by the popular hypothesis, that the suppression of perspiration is the source of innumerable evils, and that sudden vicissitudes are invariably noxious. On the other hand, however, a number of facts, standing on equally authentic record, tend to contradict this general doctrine, by showing us that rapid and great transitions, as from vapour-baths to rolling in the snow, &c. are constantly made, in some countries, with impunity, and even with advantage to the health. It remained for the genius of Dr. Currie, (a name to which the highest honours of medical science are due,) to reconcile these contradictions, upon philosophical principles, and to give us rational views of practical utility on this subject. However inconsistent with the vulgar notion, the general truth appears to be, "that, from whatever cause the heat of the body is increased, in proportion to this increase (provided no local disease has occurred, and the body is not already in a state in which it is rapidly parting with its heat,) is the safety with which cold may be applied." Medical Reports, p. 104 and 123. 2nd. edit. The numerous apparent exceptions, upon which the popular opinion is founded, will be found not to invalidate this principle, if the circumstances are minutely examined. For it will then be ascertained, that the injuries which persons have suffered from the application of cold under the circumstances in question, did not arise from its agency on them *when hot*, but *when cooling, after having been heated*; when a profuse general perspiration was rapidly carrying off the heat, or when fatigue had exhausted the vigour of the system, and the power of evolving heat; and that, on the contrary, where the sensation of heat was great and steady, the heat itself steadily retained, or kept up by exertion, and the living power not debilitated by fatigue, the application of cold was safe and salutary. A brief detail of some facts will evince the justice of this conclusion.

First, then, we shall find that all the fatal effects of cold, either when internally or externally applied, have occurred in those situations, where the system, after having been much heated and enfeebled by severe exertions, was losing its preternatural heat from profuse perspiration, and, in general, also from the cessation of the exertions by which this heat was originally produced.

Dr. Currie relates one instance of death from drinking cold water under these circumstances, which occurred in his own experience. It was the case of a young man, who had been

been engaged a long time in a moſt ſevere match at fives. After it was over he ſat down on the ground, panting for breath, and covered with profuſe perſpiration. In this ſtate he called to a ſervant to bring him a pitcher of cold water juſt drawn from a pump in ſight. He held it in his hand for ſome minutes, but put it to his head as ſoon as he had recovered his breath, and drank a large quantity at once. He laid his hand on his ſtomach, and bent forwards; his countenance became pale, his breath laborious, and in a few minutes he expired.

We are told by Dr. Ruſh, that few ſummers elapſe, in which there are not inſtances of many perſons among the labouring part of the community, being thus affected in Philadelphia; and he has deſcribed the ſeries of ſymptoms more minutely. In a few minutes, he ſays, after the patient has ſwallowed the water, he is affected by a dimneſs of ſight, he ſtaggers in attempting to walk, and, unleſs ſupported, falls to the ground; he breathes with difficulty; a rattling is heard in the throat; his noſtrils and cheeks expand and contract in every act of reſpiration; his face appears ſuffuſed with blood, and of a livid colour; his extremities become cold, and his pulſe imperceptible: unleſs relief is ſpeedily obtained, the diſorder terminates in death in four or five minutes. Medical Inquiries and Obſervations, vol. i. More frequently patients are ſeized with acute ſpaſms in the breaſt and ſtomach, which are ſo painful as to produce ſyncope, and even aſphyxia.

Many caſes are related by authors, and Dr. Currie has given a detail of ſeveral, from the collection of Shenck, in which the leading circumſtances are nearly the ſame with thoſe of the example above quoted; and many facts have been incidentally recorded by hiſtorians, which alſo agree with it in the eſſential points. In Quintus Curtius, (lib. vii. cap. 5.) an account is given of the march of the army of Alexander the Great in purſuit of Beſſus, through the country of the Sogdiani, which is repreſented as deſtitute of water, ſterile, and covered with ſcorching ſands. The intolerable heat, fatigue, and thirſt of the ſoldiers in their march through this burning deſert, are deſcribed with all the florid eloquence of the hiſtorian. At length, fainting under their toils, they reached the banks of the river Oxus, where, by indulging in large draughts of the ſtream, Alexander loſt a greater number of his troops than in any of his battles. "Sed qui intemperantius hauſerant, intercluſo ſpiritu extincti ſunt; multoque major horum numerus fuit, quam ullo amiſerat prælio." A ſimilar ſtory is related by Appian (De Bellis Civil. lib. v.); and a diſaſter of the ſame kind is recorded to have occurred to the Chriſtian army in the holy wars, (Gulielm. Tyrius, lib. iii. cap. 16.). See Currie's Reports, p. 99. et ſeq. The almoſt fatal effects which enſued to Alexander himſelf, when, after a long and haraſſing march, covered with duſt and ſweat, he plunged into the Cydnus, in the ſight of his army, are to be accounted for in the ſame way. (Quint. Curt. lib. iii. cap. 5.) The heat preternaturally accumulated by exerciſe is held with little tenacity; it is diſſipated by the profuſe perſpirations; and is ſpeedily loſt, when, to theſe perſpirations is added a ſtate of reſt after fatigue. The vital power is then unable to effect any re-action, and a ſlight application of cold exhauſts the heat and the vitality of the ſyſtem.

But, *ſecondly*, experience has demonſtrated that, on the contrary, where the heat is ſteadily retained, as in the early ſtages of exerciſe, before perſpiration has diſſipated it, or fatigue has debilitated the living power; or where it is continued by ſubſequent exertion; cold drink, or the cold bath, are highly ſafe and ſalutary. Hence the Roman youth, in the heat of their exerciſe in the Campus Martius, frequently plunged into the Tiber, not only with impunity, but deriving from it a high enjoyment: and hence the ſafety of the practice of the Ruſſians, of remaining ſome time in a hot bath of from $106\frac{1}{2}°$ to $116°$ of Fahr., then rolling naked in the ſnow, and returning to the warm bath as before. In the celebrated experiments of Dr. Fordyce, ſir Charles Blagden, &c. theſe gentlemen paſſed from a room, heated to upwards of 200°, naked, to the cold air, yet no one received the leaſt injury. The heat of the body and the action of the arterial ſyſtem were here increaſed; but had they continued expoſed naked to the cold air, till the heat ſunk as low as its natural ſtandard, and the heart and arteries ſubſided into their uſual ſtate of action, their ſituation would have been very hazardous.

From the preceding ſtatements then, it is evident, that the application of cold to the body, when heated, is always ſafe, while the heat is kept up by exertion, and while there is ſtill a ſufficient power remaining in the conſtitution of generating heat. Perhaps the ſteadineſs of the ſenſation of warmth, or at leaſt the abſence of chillineſs, is the beſt teſt of this ſafety. Hence the danger of a popular practice, of waiting till a degree of coolneſs has taken place, before quitting a hot room, or before going into a cold bath, is ſufficiently obvious; and the frequent bad conſequences of leaving hot rooms are moſt frequently the effect of this imprudent practice. We doubt whether any perſon ever received an injury from cold, after leaving a heated aſſembly, if he left it while he continued warm, and either by exerciſe in the air, or by a warm covering, kept up that warmth in ſome degree till he reached his home. And with reſpect to the cold bath, every judicious phyſician now recommends all who are delicate and infirm, to uſe ſuch a degree of exerciſe before immerſion, as may produce ſome increaſed action of the veſſels, with ſome increaſe of heat, and thus ſecure a degree of re-action under the ſhock. Thoſe who, being heated and beginning to perſpire, wait on the edge of the bath until they are perfectly cooled, and then plunge into the water, often feel a ſudden chillineſs and ſhivering, which are alarming and dangerous. In ſuch caſes the injury is generally imputed to going into the water too warm, whereas in truth it ariſes from going in too cold. See Currie's Reports, p. 109. Buchan on Sea-Bathing.

Some controverſy has been maintained among phyſicians as to the mode of action of cold on the living body, and ſome apparent inconſiſtency is to be found in the language of writers, when treating on this ſubject. Thus Dr. Cullen mentions the *ſtimulant* operation of cold, as well as the *tonic*, and the contrary, or *ſedative* operation of the ſame agent. This has ariſen from not diſtinguiſhing between the direct and indirect effects of cold. The direct effect of the application of cold, or, ſtrictly ſpeaking, of the abſtraction of heat, is ſimply the abſtraction of a great and general ſtimulus, *viz. heat*; and this is of neceſſity a *ſedative* operation. Hence, by its continuance, all the actions of the ſyſtem, and the functions of life, are enfeebled and ultimately deſtroyed. This, the two late ſyſtematic writers, Brown and Darwin, contend, is the only operation of cold. When again Dr. Cullen ſpeaks of the *ſtimulant* power, he means the *indirect* action of cold, or the conſequences which reſult from the ſubſequent operation of the ordinary temperature of the air, after the cold is withdrawn. Theſe conſequences are attributed by Drs. Brown and Darwin, not to the cold, but to the returning ſtimulus of heat. The diſpute, therefore, is obviouſly little more than verbal. The direct

direct action of cold is *fedative;* the indirect operation is *ftimulant*, or *tonic*; whatever theory we adopt on the fubject.

The mode in which the latter effect is produced, was, indeed, not explained until Dr. Brown's fyftem was promulgated. This acute, but prejudiced theorift, demonftrated this general fact in the animal economy; that whenever any accuftomed ftimulus is greatly reduced, or withdrawn, the living fyftem becomes more acutely fufceptible of ftimulation; fo that a leffer portion of ftimulus, fubfequently applied, will excite an equal action; and the ufual proportion will excite an extraordinary degree of action, or, to ufe the language of Brown, the *excitability* is accumulated during the abftraction of ftimuli. In Dr. Darwin's phrafeology the excitability is called *fenforial power*. Thus, Dr. Brown obferves, "If cold fometimes appears to ftimulate, it produces that effect not as actual cold, but either by diminifhing exceffive heat, and reducing it to its proper ftimulating temperature, or by accumulating the excitability diminifhed by exceffive ftimulus." Elements of Medicine, vol. i. fect. 37. And Dr. Darwin remarks, that, "After any part of the vafcular fyftem of the body has been long expofed to cold, the fenforial power is fo much accumulated in it, that on coming into a warm room the pain of hot-ach is produced, and inflammation and confequent mortification, owing to the greater exertion of thofe veffels, when again expofed to a moderate degree of warmth." Zoonomia, vol. ii. cl. iii. 2. 1. 17, &c. Hence, the glow on the fkin, produced by the increafed action of the cutaneous veffels, on emerging from a cold bath; and hence the face becomes of a red colour in a cold day in turning from the wind. This re-action, however, or increafed excitability of the fyftem, is in proportion to the relative vigour of the conftitution and the degree and period of the action of the cold. In a delicate habit, the vital power is fo fpeedily enfeebled by cold, that it becomes almoft incapable of fubfequent excitement; and languor, debility, palenefs, chillinefs, and fhivering enfue after immerfion in the cold bath; this ftate is fucceeded by a dry and burning heat of the fkin, which terminates in a free perfpiration, conftituting, in fact, the fimpleft form of a febrile paroxyfm.

But although it be admitted, that the action of cold, as merely confifting in the abftraction of the ftimulus of heat, is directly *fedative*, and only indirectly *ftimulant;* yet we muft contend that cold alfo exerts a different agency on the living body, which is directly ftimulant; namely, an agency on the faculty of fenfation. This fenforial power was altogether overlooked by Dr. Brown; but it is not eafy to explain why Dr. Darwin, who underftood the laws of fenfation fo well, fhould have difregarded the influence of cold upon it altogether. The ftimulating action of cold, as Dr. Currie has obferved, though fhort in duration, is powerful in degree. In the torpor of convulfion, when weaker ftimuli are unperceived, the affufion of cold water on the naked body will often excite the dormant fenfibility, and introduce a new action throughout the nervous fyftem. In the apoplectic ftate, brought on by the fumes of charcoal, this remedy is of all others the moft efficacious. In a cafe of afphyxia from this caufe, which was lately detailed to a medical fociety, by an eminent phyfician, it was remarked, that the fprinkling of cold water over the cheft and face produced an effect of ftimulation, and excited motions which were only equalled by powerful fhocks paffed from a Galvanic battery. When dogs are fuffocated in the vapour of the *grotto del cani*, it is well known that they are recovered by plunging them in the adjoining lake. The ftimulating influence of cold water in fyncope, or fainting, is a matter of vulgar obfervation. It is impoffible, therefore, to deny this influence of cold, unlefs, indeed, it fhould be faid that it is not the cold that ftimulates, but the fenfation which the cold produces; a point which it would be a wafte of time to difpute.

Befides the difference in the intenfity of the cold, in the period of its application, in its being accompanied with moifture, or with a current of air and evaporation, and other external circumftances already defcribed, as modifying its operation on the living body; there are many internal circumftances which render the body more liable to be injured by cold, or, on the contrary, enable it to refift the deleterious effects of this agent. Whatever induces debility, efpecially of the circulating fyftem, tends to enfeeble the calorific power, and, therefore, to diminifh the means of refiftance to the action of cold. Hence, long fafting, great fatigue, a previous debauch, excefs in venery, long watching, evacuations, fevere ftudy, with its concomitant, a fedentary life, all contributing to debilitate the body, render it particularly liable to fuffer from expofure to cold. Hence alfo, during fleep, (in which the heat is commonly $1\frac{1}{2}°$ lower than the ftandard of health when awake, according to Mr. Hunter), in a ftate of reft after violent exertion, and during convalefcence from difeafe, when the arterial action is languid and feeble, even flight cold is capable of producing injury, unlefs the internal heat is retained by means of warm cloathing. Injury is likewife more frequently fuftained, when one part of the body is expofed, while the reft are kept more warmly covered than ufual; or where there is a peculiar fenfibility of the conftitution, or of any particular organ of the body.

On the contrary, circumftances of an oppofite nature enable the body to refift the morbid effects of cold. Such are vigour of conftitution, efpecially of the heart and arteries; exercife, by which the action of the latter, and confequently the evolution of caloric, is increafed; and the ufe of cordials, by which the fame action is promoted. The operation of active paffions, or of vigorous attention to certain other objects, weaken the fenfation of cold, and its phyfical action on the body. Thus the aftronomer, intent on the object of his fublime fcience, it is faid, neither feels, nor is injured by, the damps or chillnefs of the night. And in certain ftates of excitement of the brain and nerves, as in fome fpecies of madnefs, cold is refifted in an extraordinary degree. Dr. Currie fays, "I have feen a young woman, once of the greateft delicacy of frame, ftruck with madnefs, lie all night on a cold floor, with hardly the covering that decency requires, when the water was frozen on the table by her, and the milk that fhe was to feed on was a mafs of ice." The influence of habit is alfo great, in enabling the body to refift the effects of cold; and the ufe of the cold bath is hence a powerful prefervative from its injuries. Cullen. Dif. Inaug. de Frigore. 1780.

The means to be adopted for the relief of thofe who have fuffered from the action of cold, will be readily underftood from a confideration of the principles, which have already been ftated. Where a ftate of torpor, or a fufpenfion of the animal functions, has been the confequence of expofure to cold, the principal object is to reftore heat to the body, and to excite the refpiration and circulation; in as much as it has already been fhewn, that the torpor of the nervous fyftem depends upon the imperfect performance of thefe functions. The patient then may be brought into a warm but well-ventilated room, and gently rubbed with warm flannels. His feet and legs may be immerfed in tepid or warm water. The action of the diaphragm and the heart, are moft readily excited by warmth and other ftimuli, applied to the pit of the ftomach. Dr. Currie invariably found in his experiments, that a bladder filled with warm water applied

plied to this part, was the most effectual mode of communicating an equable heat to the body, and removing the shiverings, the sense of chillness, and languors, produced by extreme cold in the bath. And Dr. Kellie remarked, that the good effects of friction with ammonia on the epigastric region were very striking, in exciting the action of respiration, and the motion of the heart. (See Edinburgh Med. and Surg. Journal, N° iv. p. 313.) He observed, too, that the progress of the restoration of the temperature of the body, appeared to keep pace with, and to be regulated more by, the excitement of these functions, than determined by the caloric communicated from without. The application of ammonia, or other stimulants, to the nostrils, is also useful; and as soon as the patient has so far recovered as to be able to swallow, some warm and gently stimulating drink should be given, in small quantities, from time to time.

From the accumulation of excitability, during exposure to cold, and the consequent tendency to violent inflammatory action, on the restoration of heat, it has been recommended to begin the attempt to recover persons under those circumstances, by the application of cold of a less severe degree, as by friction with snow. But the writer just quoted has suggested the propriety of discriminating between a general torpor, and the local affection in a frost-bitten limb. In the latter case, where, notwithstanding the injury done to a part, the general powers of the system remain excitable, heat must be very slowly and gradually communicated, or inflammation, gangrene, and loss of the part ensue. But in the former occurrence there does not appear to be the same danger of violent reaction, or of destroying, by premature stimulation, the accumulated sensibility, where the sensorial functions have been altogether suspended.

When disorder has been produced by drinking large quantities of cold water during profuse perspiration, after violent exercise, two remedies have been found useful; namely, a bladder filled with water heated to 110° or 115° of Fahrenheit, and the tincture of opium; the latter of which is recommended by Dr. Rush, and the combination of the two by Dr. Currie. "I know but one certain remedy for this disease," says Dr. Rush, "and that is *liquid laudanum*. The doses of it, as in other cases of spasm, should be proportioned to the violence of the disease. From a tea-spoonful to near a table-spoonful has been given in some instances before relief has been obtained. Where the powers of life appear to be suddenly suspended, the same remedies should be used which have been so successfully employed in recovering persons supposed to be dead from drowning." Med. Inq. & Obs. vol. i. p. 152.

II. *Of the Effects of Cold in producing different Diseases.*— It is well known, that the application of cold, in very moderate degrees, whether the body were previously of its natural temperature, or had been heated above that point, though incapable of producing the fatal consequences before enumerated, is nevertheless productive of numerous diseases. We have already remarked, that, in a person of a delicate constitution, immersion in cold water so far sinks the calorific powers, as to leave a great chillness, shivering, and languor on emersion, which, by a law of the animal economy not satisfactorily understood, is succeeded by a dry burning heat of the skin, quick pulse, and thirst, constituting a febrile paroxysm, of the simplest form. Now, exposure to cold, especially *after* having been heated, produces, in many persons, a similar febrile state. If it subsides in the space of 24 or 48 hours, it is denominated an *ephemera*, or fever of a day. Most commonly it remains longer, and is accompanied with symptoms of catarrh, with a diminution of the discharge from the skin. This disorder is so common a consequence of such exposure, that it is denominated vulgarly *a cold*. See CATARRH. According to the predisposition of the constitution, however, or the particular exposure or susceptibility of parts, a local inflammatory affection of one part or other, generally accompanies the febrile state. Hence we see the different forms of catarrh; inflammations of the eyes, throat, lungs, bowels, &c.; rheumatism, erysipelas, and other inflammatory diseases.

Since the experiments of Sanctorius attracted the public attention to the discharge of perspirable fluids from the skin, a great importance has been attached to the regularity of this discharge, and all the morbid effects of cold are still attributed by the vulgar to the interruption or suppression of it. This notion is apparently countenanced by the dry state of the skin during the febrile state which ensues; and by the termination of the fever, when a free perspiration again breaks forth. But it is more probable that those complaints arise from the irregularity of the circulation, and the congestion of blood in some parts, and diminution of it in others; the diminution of the distension and action of the vessels of any part being generally followed by an increase of both (by the law of excitability), which, in those cases, amounts to inflammation. Hence the parts most frequently disordered by cold, are those which are most exposed to its action, as the limbs, lungs, and throat; and rheumatism, catarrh, and inflammation of the throat, are the most common diseases: and those internal parts, which are most affected by the diminished circulation of the surface, as the bowels, also suffer considerably; whence dysentery and diarrhœa are frequent consequences of exposure to cold.

In all the attempts which have been made to pass the winter in extremely cold climates, the *scurvy* appears to have been the most fatal disease. It becomes therefore a subject of important inquiry, whether this dreadful malady is caused by the *cold*, or by the diet and other circumstances, and what means are the most effectual in preventing its occurrence. Dr. Aikin has collected together several accounts of such attempts in the first volume of the Memoirs of the Lit. and Philos. Society of Manchester, p. 89, et seq. from which some important inferences relative to these inquiries may be deduced. It is remarkable, that those who were compelled by accident, and without a supply of provisions, to pass the cold season in those inclement regions, were nearly all preserved; while those who were left by design, and with plenty of stores, all perished in the scurvy.

Capt. Monck, a Dane, in 1619, wintered in Hudson's bay, lat. 63° 20′, with the crews of two ships, well provided with necessaries; the crews amounted to sixty-four persons, all of whom, except the captain and two men, perished. In 1633, two trials were made by the Dutch of establishing wintering-places at their northern fisheries; the one at Spitzbergen, the other on the coast of Greenland, in latitudes about 77° or 78°. Seven sailors were left at each place, amply furnished with every article of cloathing, provision, and utensils, which were thought necessary or useful in such a situation. The journals of both companies are preserved, but they were all found dead on the return of the vessels in the spring.

On the other hand, Capt. James, an Englishman, wintered on an island in Hudson's bay, with a crew of twenty-two, of whom only two died. They were all affected with the scurvy, but, weak and sick as they were, compelled to labour hard out of doors, during the greatest inclemency of the season, in building a pinnace. Two other instances, one of eight Englishmen, the other of four Russians, left by accident, and destitute of provision, in Spitzbergen, are recorded,

corded; the whole of the former returned home the enfuing fpring; the latter all furvived fix years on the ifland, when one died, and the three others were refcued.

The *three* principal circumftances which diftinguifh the fatal attempts from thofe which fucceeded, are, that, in the former inftances, the men fed on *falt provifions*, drank *fpirituous liquors*, and lived in *indolence;* whereas the men who furvived the winters, and were but flightly affected by, or altogether efcaped, the fcurvy, fed upon *frefh* animal food, or at leaft preferved *without falt*; they drank *water* only, and ufed much *exercife*. On the value of frefh meat and exercife, as preventives of difeafe, it is unneceffary to comment. With refpect to the ufe of fpirituous liquors, the preceding facts are extremely important and fatisfactory. Thefe pernicious liquors, indeed, are now generally underftood to be prejudicial during fevere and continued cold, although they afford fome fupport againft the temporary effects of cold and moifture. The brief elevation which they produce, is a very fallacious token of their good effects, as it is always fucceeded by the greater depreffion, and therefore tends rather to exhauft, than to invigorate, the principle of vitality.

The popular opinion in regard to the influence of cold on the health, is, in this country, founded altogether in error. During a mild winter, complaints of the unwholefomenefs of the feafon are heard perpetually, and the falubrity of froft is generally extolled. Now the fact is entirely the reverfe, as the experience of every phyfician will evince. Dr. Fothergill fays, "it has been frequently obferved, and, as far as the bills of mortality may be depended on, is demonftrable, that an excefs of wet with moderate warmth, is not fo injurious to our conftitutions as a fevere cold feafon." Obfervations on Weather and Difeafes, Nov. 1751. And again, Dec. 1757, he remarks, "that no weather is in common fo little productive of acute and fatal difeafes, as the warm and the moift, nor any fo dangerous, in thefe refpects, as the oppofite:" this fact is alfo confirmed by Dr. Willan. Reports on Difeafes in London, p. 211. Dr. Heberden has fhewn, that, of the two fucceffive winters of 1794-5, and 1795-6, the former was the coldeft, the latter the warmeft, of which any regular account has been kept in this country, and the comparative mortality was not lefs remarkable than the temperature. "For in five weeks, between the 31ft of December, 1794, and the 3d of February, 1795, the whole number of burials amounted to 2823; and in an equal period of five weeks, between the 30th of December, 1795, and the 2d of February, 1796, it was 1471; fo that the excefs of the mortality in January, 1795, (the cold feafon) above that of January, 1796, (the mild feafon) was not lefs than 1352 perfons; a number fufficient furely to awaken the attention of the moft prejudiced admirer of a frofty winter." Philof. Tranfac. for 1796. The moft remarkable effect of a cold winter is apparent in the difeafes of old people; a mild winter, is, indeed, a year's refpite from death to many of the aged. "It is curious to obferve," fays Dr. Heberden, "among thofe who are faid, in the bills, to die above 60 years of age, how regular the tide of mortality follows the influence of this prevailing caufe; fo that a perfon, ufed to fuch inquiries, may form no contemptible judgment of the feverity of any of our winter months, merely by attending to this circumftance. Thus their number in January, 1796, was not much above one fifth of that in 1795." All the chronic difeafes of this country feem to be hurried on to a premature termination by a cold winter. In fhort, if there be any whofe lungs are tender, any whofe conftitution has been impaired by age, intemperance, or difeafe, he will be liable to have all his complaints increafed, and all his infirmities aggravated by fuch a feafon.

III. *Of the Effects of Cold as a Remedy in certain Difeafes.*—Although the action of cold on the living body, whether by directly reducing the powers of the vafcular, and nervous fyftems, by occafioning great irregularities of the circulation, or by accumulating the excitability, is a prolific fource of difeafes; it is fitted, at the fame time, by thefe powerful qualities, to counteract many of the morbid actions of the conftitution, and to arreft fome of its moft fatal diforders. Hence, from the time of Hippocrates downwards, it has been claffed among the moft active remedies which the art of medicine is poffeffed of, more efpecially in the febrile and inflammatory complaints. The writings of that extraordinary man, as well as thofe of Galen, Celfus, and moft of the celebrated phyficians whofe works have come down to us, contain many fuggeftions, both as to the internal and external application of cold; and a hoft of modern writers have commented on its ufe. In our own country it was propofed as an almoft univerfal remedy by Smith; and Dr. Hancock wrote a treatife on the fubject in the early part of the 18th century, under the title of "Febrifugum Magnum," which excited fome controverfy. But in Spain and Italy the ufe of cold water obtained, about the fame period, a greater and more general reputation, than in any of the other countries of Europe. This treatment was celebrated under the title of "Diæta Aquea." See Dr. Cyrillus's Account of it. Philof. Tranfac. vol. xxxvi.

But although the ufe of cold, as a remedy, is fupported by the fanction of antiquity, and by a feries of fucceeding authorities, it has been recommended, efpecially in febrile diforders, in a vague indifcriminate and empirical manner. It was referved for a medical philofopher of the prefent age, to determine the circumftances which render its employment in fevers fafe and falutary, and to point out the nature of its operation on clear and rational principles. We allude to Dr. Currie of Liverpool, whofe name we have already frequently mentioned. From the ftatement of the facts and principles before laid down, the reader will eafily comprehend the practical rules and cautions which muft be obferved in the application of cold to febrile difeafes.

We have already feen, from many facts and experiments, that wherever the heat of the body is increafed above its natural degree, and is retained fteadily, the action of cold is fafe, pleafant, and falutary. Now in *continued* fevers, the heat is retained in general with a tenacity much greater than when it is the confequence of temporary exertion, or of expofure to heat from without. There is, in the febrile ftate, an inflammatory conftriction of the cutaneous veffels, which tends at once to keep up the febrile action, and to prevent the flow of perfpiration, the great refrigerating procefs of the conftitution. Its fafety, therefore, in the hot ftages of *continued* fever, is decided and complete. But it is, moreover, extremely falutary and remedial in various ways. In the firft place, the fenfation of heat is one of the greateft fources of irritation in fever, and therefore tends to augment and to continue the febrile action, and to prevent the refrefhment of fleep. The operation of cold, by relieving that fenfation, contributes materially to leffen the febrile actions, and to footh the patient to repofe, at a time when all opiates are unable to effect that purpofe, but rather aggravate the reftleffnefs. Secondly, it has been proved by the experiments of Dr. Alexander and Dr. Currie, that a confiderable elevation of the heat of the body, above the ftandard of health, is incompatible with the procefs of perfpiration. Thus at the temperature of 104° or 105° of Fahr. the veffels of the fkin remain obftinately conftricted, the fkin continues dry,

dry, and pungently hot to the touch of the byſtander; and it is only when it is reduced to 99° or 100°, that the orifices of the veſſels relax, and a free perſpiration diminiſhes the heat, and moderates the febrile condition. Hence the obvious abſurdity of attempting to force ſweats, by covering the patient with a load of bedclothes, a practice ſtill unfortunately prevalent among the vulgar and the ignorant, but which all intelligent practitioners have long ago abandoned. In fact, the only means of exciting perſpiration, under ſuch high temperatures, is to *cool* the body to that lower degree at which the veſſels can relax and pour out their fluids. In fevers, therefore, as in health, *when there is no ſenſe of chillineſs preſent, when the heat of the ſurface is ſteadily above what is natural, and when there is no general or profuſe perſpiration*, the free uſe of cold drink, and the affuſion of cold water over the ſkin, are the moſt ſalutary remedies which can be adopted, as ample experience has now unequivocally decided. The conſequences of the waſhing of the body with cold water, or of the uſe of the ſhower-bath, in *typhus* fever, under the circumſtances juſt quoted, are almoſt invariably the following, as we have witneſſed in the London Houſe of Recovery. As ſoon as the patient is returned to bed, a gentle, ſometimes a profuſe, perſpiration breaks out, and a calm and quiet ſleep enſues; the actual heat of the ſurface and the diſtreſſing ſenſation of heat, are greatly diminiſhed, the pulſe becomes much leſs frequent, the tongue cleaner and moiſt, the pains of the head and limbs are alleviated, and the whole febrile condition is relieved, and its courſe rendered milder, and conſiderably abridged. This relief is the more effectual and permanent, in proportion as the remedy is more early reſorted to. When it is employed on or before the third day of the fever, in the form of affuſion, by means of a bucket of water, or the ſhower bath, it ſometimes produces a complete ſolution of the diſeaſe; but after that period, its effect is merely to relieve the ſymptoms, and, eſpecially if repeated when the heat returns, to bring the diſeaſe to a ſpeedy happy termination. In the former caſe, the great operation is attributed to *the ſhock* produced by the ſtrong ſenſation of cold; which, like other violent operations, ſuch as an emetic, a briſk purgative, &c. adminiſtered in the beginning, diſſevers the catenation of ſymptoms, which, by delay, become indiſſoluble by medicine.

Experience has now confirmed the great benefit ariſing from the application of cold water to the ſurface of the body, according to the practical precept before quoted, in typhus fever, whether originating from contagion, or other cauſes; in the ſynochus, or ſub-inflammatory fever of ſummer, in this climate; and alſo in the exanthemata, as in the eruptive fever of ſmall-pox, in which the fever and ſubſequent eruption are rendered extremely mild; and, above all, in the ſcarlet fever, in which the heat of the body riſes higher than in any other febrile diſeaſe of this country. Several remarkable inſtances of the rapid alleviation of this ſevere diſeaſe are related, which occurred in the family of Dr. Gregory, at Edinburgh, and among Dr. Currie's own children. Reports, vol. ii. In the plague, ſeveral accidents have occurred, which render it probable that cold water would be of the higheſt benefit in that terrible diſeaſe. M. Deſgenettes, phyſician to the French army in Egypt, relates that a miner, attacked by the plague, during the expedition into Syria, eſcaped naked, during a violent delirium, from the fort of Cathieth, and wandered nearly three weeks in the deſert. Two buboes, which he had upon him at that time, ſuppurated and healed of themſelves. This man perfectly recovered. An artilleryman alſo, who had two buboes and an anthrax, made his eſcape from the lazaretto of Boulak, on the day of his being admitted, and in a violent delirium precipitated himſelf into the Nile. He was taken up about half an hour afterwards, below Embabeth, by the people of that village; and he afterwards perfectly recovered. Hiſtoire Medicale de l'Armee d'Orient, p. 249. Theſe extraordinary cures correſpond perfectly with a number of ſtriking facts of the ſame kind, all pointing out the powerful inſtinct by which, in the delirium of the plague, as in other burning fevers, the patient is impelled to ſeek the moſt eaſy and obvious modes of relief. "How fruitleſs and how perverted," Dr. Currie remarks on theſe facts, "are the efforts by which learning and ſcience have attempted to combat this fatal diſeaſe! The beſt remedies for the plague were probably miſſed by the phyſicians both of France and England: they were not to be traced in the prevailing ſyſtems of medicine, or in the pharmacy of our ſhops; but it is probable they might have been found, in the refreſhment of the breeze, in the dews of the night, and in the waters of the Nile." The application of cold water to the ſkin, in the yellow fever of the Weſt Indies, has been attended with great benefit. For the evidence on this ſubject the reader may conſult Dr. Currie's ſecond volume of Reports. Dr. Jackſon's Treatiſe on the Fevers of Jamaica. Dr. Chiſholm's Eſſay on the malignant peſtilential Fever of the Weſt Indies. Dr. Stock's Medical Collections on the Effects of Cold, &c. &c.

In *intermittent* fever the preternatural heat is retained more feebly than in continued fever; and, therefore, the uſe of cold muſt be reſorted to with more caution. In the cold fit, when there is not only a ſenſation of great cold, but an actual diminution of the heat, as ſhewn by the thermometer, its application would be extremely deleterious; but experience has ſhewn, that *when the hot ſtage is fully formed*, the affuſion of cold water ſpeedily brings on the ſweating ſtage, and ſhortens the paroxyſm. Dr. Currie has related a caſe of tertian intermittent, of three months ſtanding, which had reſiſted every medicine, but of which only one paroxyſm occurred after the cold affuſion had been uſed, the bark being taken in the interval. Indeed he almoſt always found the cold affuſion produce an immediate ſolution of the fit; but, in general, if no remedy were uſed in the intermiſſion, the fever returned at its uſual period. In ſome inſtances, however, the ſucceeding paroxyſm was prevented by uſing the cold affuſion about an hour previous to its expected return; and the diſeaſe ultimately removed by continuing this practice through four or five of the following periods. But the uſe of the cold affuſion in the abſence of this fever, requires a conſtitution in a great meaſure unbroken, to render it ſafe.

In recommending the application of cold water to the ſkin as a remedy in fevers, an expreſs exception is made againſt it, during the feveriſh chill, or after the perſpiration has begun to flow profuſely, and more eſpecially after it has continued to flow profuſely, for ſome time. An exception is alſo made againſt its being employed in the latter end of fever, when the ſtrength is much exhauſted, and the heat is ſometimes as low or lower than the temperature of health. We ſpeak at preſent of fevers unaccompanied by any viſceral inflammation. The only caution, then, which is requiſite is, *that the heat of the body be ſteadily above the natural degree, and that there be no chillineſs on the one hand, nor profuſe perſpiration on the other.* Theſe obſervations apply equally to the uſe of cold drink, as to the external application of cold water.

If the aſperſion of cold water on the ſurface of the body be uſed during the cold ſtage of the paroxyſm of fever, the reſpiration is nearly ſuſpended; the pulſe becomes fluttering, feeble, and of an incalculable frequency; the ſurface and the extremities become doubly cold and ſhrivelled, and the patient ſeems to ſtruggle with the pangs of inſtant diſſolution. Conſequences, not leſs alarming, enſue, if the cold is applied during

during profuse perspiration, when the heat is rapidly sinking; and the application is sometimes equally hazardous, when the heat, measured by the thermometer, is less than, or only equal to, the natural heat, though the patient should feel no degree of chilliness. This is especially the case towards the last stages of fever, when the powers of life are too weak to sustain so powerful a shock. When these alarming symptoms have been produced by accident or inadvertence on the part of the attendants, frictions on the surface, and particularly on the extremities, should be employed; a bladder filled with warm water, of the heat of 110° or 120°, should be applied to the pit of the stomach; and cordials cautiously administered in small quantities.

With respect to the modes in which external cold may be applied to the body, it may be observed, that circumstances will determine the eligibility of each. In the commencement of fever, where the object is to cut-short the disease, by the shock of the sensation of cold, as well as by the sudden abstraction of the stimulus of heat, the *cold affusion* is to be preferred. This is performed by throwing a bucket full of water over the naked body of the patient; the shower-bath is also a convenient mode of affusion. But where the simple cooling of the body is the object of the practice, the skin may be washed with cold water alone, or with a mixture of vinegar, or common salt, by means of a sponge. This mode seems preferable in all cases in which great re-action of the system would be detrimental; as it may be regulated according to the heat, and the state of the sensations of the patient, so as to avoid, in a considerable degree, the flush of heat which ensues, after a momentary cold. The affusion of *tepid* water, *i. e.* of the heat of 87° to 97° of Fahrenheit, may be advantageously used with the same view. "The tepid affusion," Dr. Currie remarks, "is little, if at all, stimulating; and does not, like the cold affusion, rouse the system to those actions by which heat is evolved, and the effects of external cold are resisted. Where the object is to diminish heat, that may be obtained with great certainty by the repeated use of the tepid affusion, suffering the surface of the body to be exposed in the interval to the external air; and if the beams of the sun are excluded, and a stream of wind blows over it, the heat may be thus reduced where cold water cannot be procured; even in the warmest regions of the earth; on the plains of Bengal, or the sands of Arabia. I have accordingly employed the tepid affusion very generally in those feverish affections, where the morbid actions are weakly catenated, depending rather on the stimulus of preternatural heat, than on contagion, miasmata, the morbid contents of the stomach and bowels, or local inflammatory affection. Of this kind are a great part of the feverish affections of children, in which the tepid affusion is a valuable remedy. It very generally produces a considerable diminution of heat, a diminished frequency of the pulse and respiration, and a tendency to repose and sleep. I have used it also in feverish disorders of various kinds where the lungs are oppressed, and the respiration laborious, and where, of course, the oppression might be dangerously augmented by the sudden stimulus of the cold affusion. It is also applicable to every case of fever in which the cold affusion is recommended, and those may receive much benefit from it, whose fears or whose feebleness deter them from that energetic remedy." Vol. i. p. 69.

It remains to be determined by experience, to what extent the application of cold water to the surface of the body may be advantageously employed, where there is active inflammation in any of the more important organs, as in the lungs, liver, &c. Dr. Currie has collected abundant evidence, from his correspondents, of the safety of cold affusion in typhus fever, when accompanied with a cough, and other catarrhal symptoms. We have used the shower-bath, under such circumstances, in several cases; as well as in fever, combined with inflammation of the tonsils, and with dysenteric affection of the bowels, not only with impunity, but with relief, as well to the febrile as to the inflammatory symptoms.

In all cases of active inflammation, to which topical remedies can be applied, the application of cold is, next to the detraction of blood, the most powerful remedy. In these instances, as the object is simply the diminution of heat, the application of cold must not be sudden and temporary, but considerable in degree, and permanent in duration, so as to prevent any local re-action. Hence the success with which ice and snow, and the clay cap, are applied to the head and other parts, for the purpose of preventing or reducing inflammation. The saturnine and other lotions, which are employed in inflammation of the eyes, &c. seem to owe their powers principally to their cold temperature; and many of the popular remedies in such complaints are useful on this principle only.

In rheumatism, and even gout, the application of cold has, in all ages, been freely recommended by many practitioners. Hippocrates and Celsus employed it largely; and in modern times its benefits have not been overlooked. Dr. Heberden informs us, that "the great Dr. Harvey, upon the first approach of gouty pains in his foot, would instantly put them off by plunging his leg into a pail of cold water." This practice is now recommended by Dr. Kinglake, as invariably safe, and speedily curative; and we doubt not, that, in a majority of cases, where the constitution remains unbroken, and the gouty inflammation is active, such will be the event. We have yet to learn, however, under what circumstances the danger of repulsion, which is perhaps not altogether imaginary, occurs. In the more local attacks of acute rheumatism, or what is commonly called rheumatic-gout, we have seen the application of cold water to the inflamed joints very beneficial.

In the commencement of the painful inflammation produced by fire, whether by burning or scalding, the free use of cold is rapidly beneficial, in relieving the pain, and removing the inflammatory symptoms. A slight burn or scald, if the part be plunged into cold water, and detained there, or on the frequent repetition of the immersion, is frequently cured in a short space of time. The following striking fact is related in the New York Medical Repository, vol. i. p. 538. "Two brothers, apprentices to a hatter, were employed in taking hats from a boiler, and rinsing them out in a very large tub of cold water. Some dispute arising, one of them lifted the other in his arms, and seated him directly in the boiler; but being instantly struck with terror at what he had done; without loosing his hold, he again lifted him from the boiler, and seated him in the tub of cold water. The youth, who had been thus hurried through these extremes of temperature, had on a pair of wide trowsers, and received no other injury, than a narrow blister, which was formed directly under the waistband, and encircled his body."

There is another important class of diseases, in which, as well as in febrile and inflammatory complaints, the application of cold is one of the most active remedies that we possess; namely, *spasmodic*, or *convulsive* diseases. In these, however, the object is not, as in the former, the sedative operation of abstracting heat, and thus diminishing vascular action; it is the *stimulant* effect of cold, the strong impression on the sensations, by which the morbid catenations are dissevered, of which we avail ourselves in treating spasmodic diseases. It is, therefore, only the affusion of cold water, or the sudden immersion in the cold bath, which is serviceable in these maladies; and the chief benefit derived from the application

 of

of cold in these cases, "depends on its being used in the *paroxysm of convulsion*; its efficacy consists in resolving or abating the paroxysm; and when this effect is produced, the return of the paroxysm is greatly retarded, if not entirely prevented." Currie, Reports p. 133. In spasmodic diseases, which do not arise to general convulsion, the cold bath is of little efficacy.

The cold bath and cold affusion have been employed for the cure of convulsive disorders from very early times; there was a great difference of opinion, however, among the ancients as to their good effects. Hippocrates recommends the use of them, and Galen supports the same doctrine; while Paul Œgineta and others assert the insufficiency, and even danger, of these expedients. The continental writers of the last two centuries have detailed numerous instances of their good effects. In that terrible disease, the tetanus, the cold affusion appears to be the most effectual remedy, which has hitherto been adopted. Hippocrates recommends that a quantity of cold water should be poured over the patient in the convulsions of tetanus, with a view of exciting a febrile re-action; as he had observed (Aphorism. 57. sect. 4.) that a fever, supervening on a spasm or tetanus, removes the disease. He adds a caution to this advice, that the practice must not be used, except in summer; nor unless the patient be young, and of a full habit of body, and the disease do not originate from a wound. Aph. 21. sect. 5. In the West Indies, where this disease is of frequent occurrence, the affusion of cold water is said by Dr. Moseley, to have been found by far the most efficacious remedy, during the last fifty years. (Treatise on Tropical diseases. p. 491.) Dr. Currie has related several cases in which it was successful, even though the disease was the consequence of a wound; in which case, it appears that the father of physic relinquished the convulsions to nature, as incurable. Dr. Wright, who first employed the cold affusion in fever, used it also with success in tetanus. And the writer of this article has witnessed one case, which, although originating from a wound in the heel, made by an axe, was successfully treated by the cold affusion, combined with free doses of opium.

"In the *hysteric* paroxysm," Dr. Currie affirms, "the cold bath, or indeed the plentiful affusion of cold water, is an infallible remedy. Those who suppose that the terror it occasions ought, in this case, to prevent our having recourse to it, are, in my opinion, mistaken. Though the hysteric paroxysm be the offspring of passion, it is never occasioned, I will venture to assert, by the passion of fear. A sense of danger will always, I believe, prevent it; or indeed a powerful dread of any kind. I have known a tub of cold water kept in readiness, with the certainty of being plunged into it on the recurrence of the paroxysm, cure this disease, without the remedy being ever actually tried. I know the hysteric paroxysm often takes place when *danger is over*, but that is another case."

In the spasmodic affection of the bowels, which constitutes *colic*, the application of cold, especially to the lower extremities, has been frequently efficacious in dissolving the spasms, and procuring evacuations. A case of obstinate constipation, which continued in spite of all the medicines, that were devised for its relief, and in which there was also extreme pain, and considerable fever, was at length completely removed by dashing cold water on the extremities, up as high as the pubes, and plunging the feet in warm water. See Edin. Med. Essays, vol. v. p. 890. Similar cases are also recorded in the Medical Transactions of the London College, vol. iii.

By the same expedient spasmodic strictures of the neck of the bladder, have been frequently removed. It is a very common practice to place children, when afflicted with a temporary suppression of urine, with their naked feet on a cold stone, or marble hearth; and in general this plan at once removes the obstruction, and causes the urine to flow. The case of an adult (a gentleman of Bristol) is related by Dr. Currie; he was instantly relieved of an obstinate stricture of the neck of the bladder, of thirty hours duration, during all which time not a drop of water had passed, by placing his feet on a marble slab, and dashing cold water over the legs and thighs; the effect was instantaneous. The urine burst from him in a full stream, and the stricture was permanently removed. The common remedies, particularly opium and bleeding, and each of them very largely, had previously been tried in vain. Reports, p. 138.

The effect of the stimulus of the sudden sensation of cold, in the state of suspended animation, occasioned by the fumes of charcoal, has been already mentioned. In the experiments made for the gratification of travellers, who visit the *grotto del cani*, the dogs that are rendered apparently lifeless from the carbonic gas, are speedily recovered on being plunged into the adjoining lake. Several experiments on other animals, in which the same phenomena were observed from the application of ice and cold water, after suffocation by carbonic acid gas, are related by Dr. Stock. See his Med. Collections before quoted, p. 120. et seq. The good effects of the same stimulus are universally known, in common cases of fainting, or syncope, from which the patient is speedily roused by sprinkling cold water on the face. The stimulating effects of this application, were, indeed, in one case of asphyxia, to which we before alluded, not less obvious than those occasioned by the Galvanic fluid.

We shall content ourselves with merely mentioning other instances of disease, in which the application of cold is of considerable value as a remedy. Such are the active hæmorrhagies; phrensy or inflammation of the brain; the early stage of the acute hydrocephalus, and of the torpor from drunkenness; and the paroxysms of acute mania. In all these maladies the cold should be applied steadily, near the parts affected, the object being to diminish the action of the vessels in those parts by abstracting the stimulus of heat. There are other diseases also, in which the sudden and temporary application of cold, in the form of the cold-bath, is efficacious, by gradually strengthening the constitution; such are scrofula; the rickets of children; and some cutaneous disorders. The same expedient is also beneficial as a preventive of several diseases, especially those which arise from exposure to cold and moisture, such as catarrh, rheumatism, inflammatory sore throat, &c. by inuring the system to the action of cold, and thus fortifying it against its deleterious effects.

COLD, the popular term for catarrh, which is the most frequent disease occasioned by the action of cold. See CATARRH.

COLD is also a disease to which horses are subject; this is usually occasioned by want of regular exercise, by overheating them in riding, and suffering them to cool too fast, or neglect of rubbing them down when they come in hot after journeys. The signs of a cold are a cough, heaviness, watery eyes, kernels about the ears and under the jaws, gleets of the nose, and rattles, in breathing, &c. Bleedings, hot mashes of bran and water, and moderate exercise will, in most cases, be an effectual remedy. To these may be added balls consisting of warm opening ingredients; Dr. Bracken prescribes the following; take anniseed, carraway seed, and greater cardamoms, finely powdered, of each one ounce, two ounces of flower of brimstone, one ounce and a half of turmeric in fine powder, two drams of saffron, two ounces of Spanish juice dissolved in water, half an ounce of oil of anniseed, one ounce and a half

half of liquorice powder, and a fufficient quantity of wheat flour; let thefe ingredients be well beat in a mortar and made into a ftiff pafte; and given in fmall quantities about the fize of a pullet's egg. See COUGH.

COLD *Fit*, in *Medicine*, the firft ftage of a paroxyfm of fever, in which there is not only a fenfation of cold, but a pale and contracted fkin, and generally a diminution of the actual heat, as meafured by the thermometer. The cold ftage is moft fevere and obvious in intermittent fevers, in which it is accompanied with great fhivering, and even fhaking of the whole body, and clattering of the teeth: it is denominated by the vulgar, the *ague*, in contradiftinction to the fucceeding hot and fweating ftages, which are called the *fever*. See FEVER and AGUE.

COLD-*Bath*. See BATH, and BATHING.

COLD, *Artificial*. See FEEEZING, or THERMOMETER.

COLD *Diamargariton*. See DIAMARGARITON.

COLD *Diatragacanth*. See DIATRAGACANTH.

COLD *Diftillations*. See DISTILLATION.

COLD *Fufion*. See FUSION.

COLD *charge*, in *Farriery*, a medicine confifting of vinegar, bole, and whites of eggs, mixed to the confiftence of a poultice, and fpread over the injured part for the cure of ftrains, &c.

COLD-*finch*, in *Ornithology*, the name of a fmall bird occafionally obferved in England, and better known by the appellation of pied-fly-catcher. It is the *mufcicapa atricapilla* of Linnæus. See ATRICAPILLA.

COLD-*Afton*, in *Geography*, a vicarage in Gloucefterfhire in the hundred of Puckle-Church; the fituation of its church fteeple was determined in the "Government Trigonometrical Survey," in 1797, by obfervations from Lanfdown ftation, diftant 13,563 feet, and from Farley Down ftation, diftant 24,120 feet, and bearing 33° 43′ 21″ S.E. from the parallel to the meridian of Black-Down; whence was deduced its latitude 51° 26′ 54″.8 N. and its longitude 2° 20′ 44″.4, or 9m 24s.9 W. of Greenwich.

COLD, *Cape*, a cape at the north end of Charles ifland, on the coaft of Eaft Greenland. N. lat. 79° 6′. E. long. 10° 57′.

COLD *Spring Cove*, is fituated near Burlington, New Jerfey, America, and is remarkable for its fand and clay, ufed in the manufacture of glafs; from whence the glafsworks at Hamilton, 10 miles weft of Albany, are fupplied with thefe articles.

COLDDITZ, a town of Germany, in the circle of Upper Saxony, and circle of Leipfick; 21 miles S.E. of Leipfick, and 36 W. of Drefden.

COLDENIA, in *Botany*, (fo named by Linnæus, in honour of C. Colden, a North American botanift, who fent feveral new plants to Europe, which are defcribed in the Upfal acts for 1743.) Linn. Gen. 173. Schreb. 233. Willd. 268. Gært. 424. Juff 130. Clafs and order, *tetrandria tetragynia*. Nat. Ord. *Afperifoliæ*, Linn. *Borragineæ*, Juff.

Gen. Ch. *Cal.* Perianth, four-leaved (four-cleft, Gært.); leaves lanceolate, erect, rough with hairs. *Cor.* monopetalous, funnel-fhaped, the length of the calyx; mouth not clofed; border four-cleft, fpreading, obtufe. *Stam.* Filaments four, inferted into the tube; anthers roundifh. *Pift.* Germs four, fuperior, egg-fhaped, connate in pairs, each ending in a filiform permanent ftyle; ftigmas fimple. (Style one; ftigma bifid; Gært.) *Peric.* none. *Fruit* egg-fhaped, compreffed, fcabrous, acuminate, terminated by four beaks; Linn. (Fruit four-capfular, fcabrous, four-beaked; capfules approximating, one-feeded; Juff. *Seeds* two, two-celled, mucronate at their fummit, echinate with fhort hairs, flattened on the fide where they join, two-lobed on the outfide, forming together four regular lobes, ending in a point compofed of four upright ftyles clofe to each other; Lam. Nuts four, fmall, enclofed in a rind, united into a rounded, tetragonal, mucronate fruit; rind fungous, very thick on the back of the nuts, becoming gradually thinner, and almoft membranous on the fides; fhells bony, hard, convex, and rounded on one fide, compreffed into an acute angle on the other, one-celled; Gært.)

Eff. Ch. Calyx four-leaved. Corolla funnel-fhaped. Styles four. Seeds two, two-celled.

Sp. C. *procumbens*. Linn. Sp. Pl. Mart. Lam. Willd. Gært. tab. 68. (Teucrii facie bifnagarica tetracoccos roftrata; Pluk. Alm. tab. 64. fig. 6. Morif. Hift. 3. 423. n. 22.) *Root* annual. *Stems* trailing on the ground, a foot long, cylindrical, branched, rough with white hairs. *Leaves* alternate, egg-fhaped, rounded at their fummit, nearly feffile, deeply crenated, plaited at the ferratures, unequal at the bafe, cloathed with white hairs except in the plaits. *Flowers* pale blue, fmall, axillary, feffile. A native of the Eaft Indies. It is propagated by feeds, fown in a hot-bed in the fpring. When the plants are fit to remove, they fhould be put into feparate pots, plunged into a hot-bed of tanners' bark, and kept in the fhade till they have taken frefh root; after which they fhould have frefh air, according to the warmth of the weather, and be fparingly watered two or three times a week. They muft remain in the hot-bed, where they will flower in June, and ripen their feeds in September.

COLD-HARBOUR, in *Geography*, a houfe on the north bank of the Thames, oppofite to the town of Earith in Kent, the fituation of which was determined in the "Government Trigonometrical Survey," about the year 1798, by obfervations from Rainham fteeple, diftant 11,090 feet, and bearing 3° 1′ 31″ N.E. from the parallel to the meridian of Greenwich; and from the ftation on Purfleet Cliff, diftant 10,971 feet, and bearing 81° 1′ 59″ S.E. from the fame parallel; whence is deduced its latitude 51° 29′ 16″.5 N. and longitude 0° 11′ 19″.3 E. of Greenwich.

COLDING, or KOLDING, a town of Denmark, in the diocefe of Ripen, fituated between mountains, on the river Thueths, which runs into the Little Belt about a league below. It is an ancient town, and was formerly the refidence of many Danifh kings, who adorned it with feveral edifices. The harbour is now filled up, and its commerce almoft annihilated; 24 miles N.E. of Ripen. N. lat. 55° [illegible]′. E. long. 9° 23′.

COLDINGHAM, a town and parifh in the county of Berwick, Scotland. The town is fituated about a mile from the fea, in a reclufe vale, watered by two rivulets, which flow on either fide of it. The monaftery at Coldingham is faid to have been burnt previous to the confecration of St. Cuthbert, or about 685, and was rebuilt, according to lord Hailes, by king Edgar in 1098, who affifted at its dedication, after which it became one of the moft important in this eaftern portion of the kingdom. The diffolution of the monaftery, or fome other caufe, appears to have injured and diminifhed the town confiderably, but it has recently exhibited indications of renovation, and the inhabitants rapidly increafe. The parifh is fertile with the exception of about 600 acres, which are totally incapable of cultivation, and the peats found in the diftrict are not fufficiently folid for fuel; but the hills are not generally fo fteep as to prevent the ufe of the plough, though St. Abb's head is in the vicinity, and the coaft, compofed of crags, is confidered dangerous to the mariner. The banks of the river Eye, which flows through the parifh, are fringed with wood, and Coldingham loch, a mile weft of St. Abb's head, is a beautiful

beautiful ſheet of water of conſiderable depth, and about a mile in circumference. There are ſeveral hamlets within the pariſh, inhabited principally by farmers and weavers, and the ruins of a church are ſtill viſible on St. Abb's head. Faſt-caſtle in this neighbourhood, is entirely ſurrounded by the ſea, and muſt have been almoſt impregnable before the invention of cannon. Population in 1791, 2391.

COLDITZ, a town of Germany, in the circle of Upper Saxony, and margraviate of Meiſſen, ſituated on the Mulda; 10 miles S.E. of Leipſick.

COLDSHIRE *Iron*, ſuch as is brittle when it is cold; ſee IRON.

COLDSTREAM, in *Geography*, a town ſituated on the north ſide of the river Tweed, in the county of Berwick, Scotland, ſeems to have owed its origin to an abbey of Ciſtertain monks which ſtood within the pariſh of the ſame name. General Monk has contributed to immortalize the place, from having raiſed a regiment here, which he named the Coldſtream, previous to his victorious exertions in favour of Charles II. Since that period a portion of the royal guards have borne the title, which has never yet been ſullied, or diſhonoured; probably this is the moſt important epoch in the annals of Coldſtream. There are ſeveral tumuli in the pariſh, that are ſuppoſed to contain the remains of Chieftains ſlain in remote border wars. The roads from London to Berwick, and from the latter to Kelſo, and Dunſe to England, paſs through Coldſtream, which is admirably ſituated for manufactures, as coals are reaſonable in price, wool plentiful and excellent, and the banks of the Tweed produce great crops of corn, and feed numerous herds of cattle; yet, with all theſe advantages, and a neat bridge facilitating communication between the two kingdoms, no conſiderable trade is carried on.

The pariſh borders on the Tweed for ſeven or eight miles in length, and is about four in breadth; the ſoil on the above river is light, but inclines to clay at ſome diſtance from it, and a ſingular ſlip of barren land, termed the *Muir-Land*, divides the pariſh from eaſt to weſt. Shell and rock marle, free-ſtone, and coals, are found in abundance, and yet the latter is much neglected. Several plantations have lately been ſet to ſupply the deficiency of native trees. The principal ſeats in the pariſh are Hirſel, the reſidence of the earl of Home, who has erected two ſuperb obeliſks to the memory of his ſon, lord Dunglaſs, ſlain in the American war, and Kersfield, the manſion of Mr. Moriſon. Population of the diſtrict in 1793, 2193.

COLD-WATER, a lake of North America. N. lat. 54° 56'. W. long. 111°.

COLE, WILLIAM, in *Biography*, the moſt famous botaniſt of his time, was born at Adderbury in Oxfordſhire, in 1626, and after the uſual elementary learning he went to Merton College, Oxford, where he completed his education. He ſettled at Putney, a village near London, and publiſhed a work intitled "The Art of Simpling, or an Introduction to the Knowledge of gathering Plants," &c. and another intitled "Adam in Eden, or Nature's Paradiſe, containing a Hiſtory of Plants," &c. Upon the reſtoration of Charles II., he was appointed ſecretary to Dr. Duppa, biſhop of Wincheſter, but died in the year 1662, at the early age of 36.

COLE, WILLIAM, a learned and ingenious phyſician, who diſtinguiſhed himſelf by various publications on phyſiology, and on the practice of medicine; received his education at Oxford, where he took his degree of doctor in the year 1666. He ſoon after ſettled at Briſtol, and having acquired celebrity there, he removed to London. He had the merit of being an early convert to the opinion of the excellence of the Peruvian bark, which he preſcribed liberally and with ſucceſs in hyſterical affections, as well as in intermittents. His works abound too much with theory. Fever he ſuppoſed to be occaſioned by a depravation of the nervous fluid. His works are, "De Secretione Animali, cogitata," Oxon. 1677, 8vo. The ſecretions receive their qualities from the ſtructure of the glands, by which they are ſeparated from the blood. "An Eſſay concerning the late frequency of Apoplexies," Oxford 1689. His new hypotheſis as to the cauſe of fever, firſt publiſhed in 1694, was ſeveral times reprinted, "Conſilium ætiologicum de caſu quodam Epileptico." He recommends the miſletoe, by which he pretends to have cured the complaint. The patient, who deſcribes his caſe, ſays he was much relieved. He wrote alſo on inſenſible perſpiration, and was author of ſeveral diſſertations which were publiſhed in the "Philoſophical Tranſactions" of that time. Haller Bib. Med. Eloy. Dict. Hiſt.

COLE, in *Agriculture*, the name of a plant of the cabbage kind, which is cultivated both on account of its ſeed, and for feeding cattle and ſheep. The ſeed, by preſſure in mills contrived for the purpoſe, affords a valuable oil, and the refuſe, or cake, is uſed as a manure.

It has ſometimes the name of *rape*. Martyn, in his edition of Miller's Dictionary, ſeems to conſider cole (*braſſica napus*) as the wild plant; and rape (*napus ſativa*) as a garden or cultivated variety; but obſerves, that "the ſpecific diſtinctions are very inſufficient,"

A late writer on huſbandry remarks, that "as to the difference between cole and rape, it is hardly poſſible to diſtinguiſh them in the ſeed, but when in plants you may eaſily tell one from the other. Cole is generally intended to be eaten by ſheep, and rape to ſtand for ſeed to be manufactured into oil, which is uſed in large quantities by clothiers, and other tradeſmen, and likewiſe in phyſic. Cole is alſo often ſown for the purpoſe of ſtanding for ſeed, from which oil is made. Cole grows to a greater height when in leaf than rape, and the ſtalks are ſo ſoft and pulpy, that ſheep can eat them very near the bottom. Rape is of a hardier nature, fitter to ſtand the winter; the ſtalks are rigid, grow buſhy, and branch much; and when ſpring approaches they ſpread and yield more ſeed than cole. Theſe two ſeeds are in general, he thinks he may ſay always, intermixed; it would, therefore, be well worth while for a grower to collect with care, out of a crop, the different ſeeds, and to ſort them properly, for cole is the beſt for feeding ſheep, and rape for the purpoſe of making oil."

It is a plant which has been found to thrive in the beſt and moſt perfect manner in deep, rich, dry, friable, and kindly ſoils; but which, with plenty of manure, and deep ploughing, may be grown in moſt others. And it has been ſtated by Mr. Young, in his calendar of huſbandry, that upon fen, and peat ſoils and bogs, as well as black peaty low grounds, it thrives aſtoniſhingly, but more eſpecially when the land has been pared and burnt, which is the beſt ſort of preparation for it. But the author of the "New Farmer's Calendar," thinks that it is a plant which is not perhaps worth attention on any but rich and deep ſoils; for inſtance, thoſe luxuriant ſlips that are found by the ſea ſide, fens, or newly broken up grounds, where vaſt crops of it may be raiſed; hence it is, he ſuppoſes, we have heard ſuch different accounts of its produce and uſe.

It has been ſuggeſted by the author of "Practical Agriculture," that when grown on lands that have been long in tillage, the friable, loamy kinds are found to anſwer the beſt; but that it may be grown with perfect ſucceſs on the fenny, marſhy, and other coarſe waſte lands, that have been long in the ſtate of graſs, after being broken up and reduced into a proper ſtate of preparation. As a firſt crop, on ſuch defcriptions of lands, it is often the beft that can be employed. When fown on old tillage lands, the method of preparation is pretty much the fame as that which has been given for the common turnips; the land being ploughed over four or five times, according to the condition it may be in, a fine ftate of pulverization or tilth being requifite for the perfect growth of the crop. In this view, the firft ploughing is moftly given in the autumn, in order that the foil may lie expofed to the influence of the atmofphere, till the early part of the fpring, when it fhould again be turned over twice, at proper diftances of time from each other; and towards the beginning and middle of June, one or two additional ploughings fhould be performed upon it, in order that it may be in a fine mellow condition for the reception of the feed. But if the feed be intended to be put in upon lands that are newly broken up from the ftate of fward, they muft, fays he, be rendered perfectly clean, and in a fufficiently fine ftate of mould for the reception of the feed, either by frequent ploughing in the common way, and afterwards harrowing the furface well by light fhort-tined harrows, or by having recourfe to the practice of paring and burning. The laft is by much the moft effectual, cheap, and advantageous method, where the furface contains a large quantity of coarfe graffy matter, as it can fcarcely be reduced by any other means, without much time and trouble. This is the fort of preparation that is generally employed when the crop is intended to ftand for feed. Further, that where it is fown on the firft fort of preparation, it is the beft practice for it to fucceed wheat or barley crops. When the former, barley and oats, with grafs feeds, may be put in after it, but if the latter, it may be fucceeded to the greateft advantage by wheat, as it is found to be not only an excellent preparation for that fort of grain, but to afford it of the fineft quality; and by its being taken off early, there is fufficient time allowed for getting the land in order for the wheat crop. That where the tillage land is not in a good ftate of fertility, manure of the fame kind, and in the fame proportion as for turnips, fhould be applied, and turned in with the laft ploughing for the feed.

It is ftated in the "Effex Report on Agriculture," that cole feed is ufually prepared for by as full and complete a fallow as turnips, and no lefs quantity of manure. This, however, chiefly refpects arable land long cultivated; but newly broken up ground, efpecially, is found generally moft congenial to this feed, and vaftly the moft productive. The writer faw a ftriking inftance of this. "A fine field, as to quality of foil, was fown broad-caft with cole feed. The greater part of it had been arable time immemorial, the remainder recently broken up. The produce of the former was only between three and four quarters an acre, the latter upwards of five."

It is found in the raifing of this fort of crop, fuch feed as has been perfectly ripened, is quite frefh, and has a fine black colour, is to be preferred, as vegetating in the moft perfect and expeditious manner.

The quantity or proportion of feed that is made ufe of is, in general, from a quarter to half a peck, according to the manner of fowing that may be practifed. Where the crop is intended to be confumed as a green food for cattle, a larger proportion of feed may, however, be neceffary than where the obtaining of feed is the chief object of the cultivator. Two quarts an acre have been mentioned by Mr. Young, but fome, he fays, fow three, and he has heard of a gallon being fown.

In the Effex Survey it is fuggefted, that "from three to four pints per acre fhould be fown if intended to ftand for feed; but if defigned merely for autumn, winter, or fpring feed, more may be requifite, and even five or fix pints may not be too much."

The methods of fowing are different in different cafes; but the moft common practice is that of broad-cafting, or difperfing it in as regular a manner as poffible over the furface of the ground by the hand, covering it by means of a bufh, or other light harrow. Inftead of this it is, however, fometimes ploughed in, when cultivated on the more light and open kinds of foils, a large proportion of feed being allowed, and the furrows made narrow, with but little depth. In cafes of this fort, this has been fuggefted by Mr. Kent as preferable to the former mode.

But the drill method has alfo been practifed, the feed being depofited, to the depth of one inch, in rows; on every other land twelve inches afunder. The fuperiority of this mode, over that of the broad-caft, appears, according to Mr. Amos. to be confiderable, as the land is capable of being kept clean with lefs difficulty and expence than in the other modes.

The author of the "Experienced Farmer," fays, that "rape ought to be drilled in the fame manner as peas and turnips, with the manure in the drills; and, like peas and turnips, fhould be cleaned in the fpring by the plough. If this is properly done, it will, he thinks, make the land equal to the beft fallow in the kingdom. The falling of the leaves, and the fmothering of the crop, will keep it in quite a mellow ftate; and if the ftraw and roots are immediately cleaned off, the ground fcarified, and a fufficient quantity of feed fown, there will be a crop of rape, to be eaten by fheep, between the time of reaping the rape and of fowing wheat. This, inftead of impoverifhing, would improve the land in a very high degree, and intermix the manure in the beft manner poffible." Rape has two years rent to pay, and cannot turn out a very profitable crop, without fome management of this fort, but, by the method here recommended, you get a crop and a half in two years."

It has been fuggefted by Mr. Marfhall, as a defirable method, to fow the feed in beds, for the purpofe of being afterwards tranfplanted into the field, and fet out in the manner of cabbage plants. Half a rood of land, in this way, would, he fays, be fufficient to furnifh plants for five or fix acres. In this manner, as well as by pulling the plants from the places where they may ftand too clofe in the fields, the vacancies that frequently occur in this fort of crop, may be filled up, the work being performed by dibbles. And this Mr. Young confiders as the Flemifh culture.

The feed fhould, he thinks, be fown thick, the plants being fet out on an oat ftubble, after one ploughing.

It is, he conceives, fo great and ftriking an improvement of our culture of the fame plant, that it merits the utmoft attention; for faving a whole year is an object of the firft confequence. The tranfplanting is not performed till October, and lafts all November, if no froft; and at fuch a feafon there is no danger of the plants not fucceeding; earlier would, however, furely be better, to enable them to be ftronger rooted to withftand the frofts, which often deftroy them; but the object of the Flemings is not to give their attention to this bufinefs, till every thing that concerns wheat fowing is over. The plants are large, and two feet long; a man makes the holes with a large dibble, like the potatoe one ufed on the Effex fide of London, and men and women fix the plants at 18 inches by 10 inches, fome at a foot fquare, for which they are paid *9 liv. per manco* of land. The culture is fo common all the way to Valenciennes, that there are pieces of two, three, and four acres of feed-bed, he fays, often met with. The crop is reckoned very uncertain; fometimes it pays nothing; but in a good year, up up to 300 *liv.* the arpent (100 perches, of 24 feet), or 8 *l.* 15 *s.* the English acre. They make the crop in July, and by manuring the land, get good wheat.

In Essex "rape-seed," Mr. Vancouver observes, "is transplanted at twelve inches square upon potatoe land, at a guinea per acre; generally stands for a crop, and is always found to answer extremely well. This practice is strongly recommended where wheat straw is in much demand, as the straw of the rape-seed affords an excellent substitute for littering the straw-yards, the sheds, and the stall-fed cattle."

Another mode is likewise suggested by Mr. Marshall, which is "the transplanting the whole crops, by beginning at one side of the field, and proceeding gradually from one land to another, till the whole is finished, which would, it is believed, be highly advantageous; as in this way the land would be provided with the best plants, and such as are of equal size; and by their being placed at regular distances, the crops would ripen in a more equal manner, while at the same time free admission would be given to the hoe, and the intervals be kept clean by narrow horse-hoes for the purpose. The work is commenced about the beginning of September or October, according to circumstances, in which the plough is made use of, the plants being placed by women in a leaning position in every second furrow, about a foot apart, and the roots covered by the next furrow, after which another is added, and more plants placed in as before, proceeding in the same manner till the whole is finished. The plants, of course, stand about the distance of eighteen or twenty inches by twelve. Where land that has been pared or burned, is managed in this way, it is advised that the first, or seed-ploughing, should be in a cross direction; and that for transplanting lengthways, in order to render the land dry in the winter season.

It may be observed, however, that these latter methods of managing these crops appear better adapted for such as are designed for seed, than for those intended as green food for live-stock; as, by the perfect culture, that may be thus given them, and the use of manure, the inconveniencies attending the feeding of rape crops, may, perhaps, in a great measure, be obviated.

And it is suggested, that when cultivated for use as a green food, the seed should probably be sown more early than where the crop is to stand for seed, or be employed in both ways, but sufficiently early to get a strong leaf without running to stem the first autumn. The middle of June and the last week in July may, it is supposed, be the most proper periods. Mr. Young remarks, that, when for sheep-feed, the crop is sown all through these months, but, for seed, the first week in August will do.

Where, however, the plant is cultivated merely for the seed, it is mostly sown on such lands as have been newly broken up, either by paring and burning, or some other similar means, about July or August. But when it is to be made use of as a winter and spring food for animals, the land is prepared as above, and the seed sown about the same time as that of the turnip.

In respect to the after culture of crops of this sort, it should always be well attended to, in order that large stems may be produced. It is advised by some that the crop should be kept perfectly clean by means of hand and horse-hoeing, a practice which is not, however, by any means general among the cultivators of this kind of produce. It is, indeed, supposed by some farmers, who are in the habit of cultivating this plant, that it would answer well, and pay for the labour and trouble of having the young plants transplanted from a seed-bed, as above; a very small bed, or portion of ground, being sufficient to supply the necessary quantity of plants. By adopting this method, and setting them out upon ridges, as practised in some places for turnips, having a proper allowance of manure and suitable hoeing, the general complaint against the cultivation of this plant for seed might, it is thought, be obviated, as it is probably the weedy and slovenly state in which the crop is suffered to remain that renders it more exhausting than many other similar crops. In whatever way the cultivation may be attempted, it is evident that the land cannot be too mellow or too much pulverized, for the growth of the cole-seed plant; as it not only requires a rich soil, but also that it be in excellent tilth.

In the cases of broad-cast sowing, where the culture of the crops is afterwards attended to, it is suggested as the practice of some farmers, after the plants have attained two or three inches in height, put out six leaves, and begun to spread and shew themselves perfectly above ground, to hoe them over by means of a hand-hoe, somewhat smaller than that employed for turnip crops, setting the plants out to the distances of from six to eight or nine inches from each other, according to their vigour or strength, and the fertility of the soil. This is the only hoeing that is in general given; but in many cases, as where the land is poor and disposed to throw up weeds, much advantage may be derived from a repetition of the operation, not only in cleaning the ground, but promoting the growth of the plants, by stirring the mould round them. This should be done about a month or five weeks after the first hoeing. The expence of performing the work once is mostly from about six to seven or eight shillings the acre. But that in the row method of cultivation, whether by drilling the seed, or transplanting the young plants, the business of hoeing may be performed in a more perfect and cheap manner, on account of the great distances of the plants admitting the earth in the intervals to be stirred by the plough or horse-hoe, while hand-labour becomes only necessary between them in the rows. In this way a garden cleanness may be preserved in such field crops at no great expence.

It is stated, in the "Report of Essex," that in the rich district of Rochford hundred, they have immense crops of cole, and they are admirable farmers in the management of it. Some crops of Mr. Wright's, at the Hall, are exceedingly fine ploughed for seven times, manured with twenty loads an acre of dung, and all hoed out (though not for seed) to a foot asunder: this incomparable management, which stretches away so far beyond the common practice of the kingdom, produces, the writer says, *stalk*, which is the great value of cole; and on this fine land that stalk is as brittle as glass, the sure proof of a feeding property. These crops are mown with a strong scythe made on purpose, and carted to the farm-yard to feed bullocks, which it fattens better than any other food produced by the farm; some also scatter them on dry pastures for fattening sheep. In Lincolnshire, he remarks, they know the value of cole, but none is hoed. And Mr. Prentice, of Prittlewell, is largely in this husbandry, and his crops very fine. He is very careful in the hoeing, as he conceives that great virtue is in the stalks; he gets stalks as large as his wrist, and these are more forcing to a bullock than turnips: this is the object that makes hoeing so profitable. They are mown and carried to bullocks in yards. He finds oats are as good after cole as after turnips; but a clear fallow will give more than either. He has fed part of a field on the land and mown part, the oats were a little better after feeding. Mr. Vassall, of Eastwood, is also so well convinced of the great value of the stalk, that he does not mow but speeds up to get more, and every atom is eaten by sheep. And several feveral other cultivators in the fame diftrict find great advantage from hoeing and keeping the crops clean.

By fome it is thought, that where thefe forts of crops are confumed in their green ftate on the foil, they may be equally beneficial to the landlord and his tenant; but it is fuggefted in the "Agricultural Survey of the county of Middlefex, that, fuffering them to perfect their feed, would be putting a confiderable fum of money into the pocket of the tenant at the certain expence of the landlord."

And it is obferved by Mr. Donaldfon, that where this kind of crop is cultivated for feed, great care fhould be taken that it be not allowed to remain too long uncut; as, in that cafe, it is very apt to fhed its feeds. As foon as the pods begin to affume a brownifh colour, it fhould be reaped, and laid carefully in the ground, where it ought to remain, without moving, till it be ready for thrafhing. This is afcertained by the ftraw or ftalks becoming white, and the feed, when rubbed out, appearing black. It fhould always be thrafhed out on the field on which it grows, as it is almoft impoffible to remove it any diftance, without fhaking out a great part of the feed. The operation is ufually performed on large cloths, about twenty yards fquare; and, in order to do it expeditioufly, a great number of hands are commonly employed.

Mr. Young has remarked, that crops of rape or cole-feed are extremely different, uncertain, and liable to numerous accidents. "They muft," fays he, "be conducted with great fpirit, or the lofs will probably not be fmall. The principal point is to make good ufe of fine weather; for, as they muft be thrafhed as faft as reaped, or at leaft without being houfed or ftacked like other crops, they require a greater number of hands in proportion to the land, than any other part of hufbandry. The reaping is very delicate work; for, if the men are not careful, they will fhed much of the feed. Moving it to the thrafhing floor is another work that requires attention; the beft way is to make little waggons, on four wheels, with poles, and cloths ftrained over them: the diameter of the wheels about two feet; the cloth-body five feet wide, fix long, and two deep, and drawn by one horfe; the whole expence not more than 30 or 40*s*." He has, in large farms, feen feveral of thefe at work at a time in one field. The rape is lifted from the ground gently, and dropped at once into thefe machines without any lofs; they carry it to the thrafhers, who keep hard at work, being fupplied from the waggons as faft as they come, by one fet of men, and their ftraw moved off the floor by another fet; and many hands of all forts being employed, a great breadth of land is finifhed in a day. Some ufe fledges prepared in the fame way. All is, he fays, ftopped by rain, and the crop much damaged; it is therefore of very great confequence to throw in as many people as poffible, men, women, and boys, to make the greateft ufe of fine weather.

The author of the "Rural Economy of Yorkfhire" has obferved, that a public rape thrafhing, conducted as it is in the vale diftrict of this county, is one of the moft ftriking fcenes which occur in the field of rural practice. "Contending armies," fays he, "can fcarcely exhibit, to the diftant eye, greater tumult; nor can the parade boaft of better difcipline, than may fometimes be obferved in a well-conducted rape-thrafhing.

"If the quantity to be thrafhed be large, as 20 or 30 acres, the whole country, for many miles round, are collected. The days of thrafhing are confidered as *public days;* the lord of the harveft keeping *open field,* for all who choofe to enter; ample provifion of meat and drink being made for this purpofe. A wake or a fair is not a fcene of greater jollity.

"It is not common, however, for unbidden guefts to go to thefe rural meetings, without affifting, or at leaft offering their fervices to affift, in forwarding the bufinefs of the day. But to make fure of hands for the more laborious departments, men and women are previoufly retained with wages, over and above the fpoils of the feaft.

"Alfo previous to the day of thrafhing, a "rape-cloth," "carrying cloths," and other neceffaries, are to be provided. The cloths are in the hands of a few men who let them out at fo much a day, or fo much an acre. A rape-cloth of the largeft fize meafures twenty yards fquare, weighing more than half a ton weight. Heffen is the ufual material of which it is made. The hire of fuch a cloth is 15*s.* a day.

"Alfo, before the thrafhing, the rape and the ftubble are to be cleared away from the place, or places, (if the piece be large) where the thrafhing-floor is to be made, the clods being taken off, and the hollows filled up where the cloth is intended to be laid.

"The bufinefs of the day is thus conducted: the men are divided into carriers, thrafhers, and floor-men. Women fill the carrying-cloths, and boys hold them while filling. Thefe cloths are made of canvafs, about fix feet fquare, with poles fixed on two oppofite fides, in the manner of a rolling map; openings being left in the middle between the poles and the canvafs, for two men to run their arms through, one on either fide the poles, refting by them on the men's fhoulders; the cloth filled with rape hanging between them. In thefe cloths the whole of the crop is carried to the thrafhing-floor.

"The floor-men are divided into layers-on, turners, takers-off, rake-men, riddlers, &c. &c. &c.

"The rape to be thrafhed is fpread thin upon the cloth, in a circle as large as the cloth will contain.

"The thrafhers move continually in this ring; marching with a flow ftep, in pairs and in two divifions; the individuals of each divifion following one another, as clofely as the nature of their employment will allow them.

"The firft divifion are preceded by the layers-on, and followed by the turners, and clofe upon the rear of the fecond divifion follow the takers-off, who, with wooden tined forks, fhake and throw off the ftraw, which is piled in heaps by others, with longer implements.

"Finally, the rake-men run off the feed with the ends of their rakes thruft before them, forcing the feed into receffes formed within the ring, or upon the corners of the cloth; where groups of fillers, riddlers, &c. &c. are employed in feparating the feed from the principal parts of the pods and fhort ftraws which are beat off in thrafhing; while others are equally bufy in putting the unwinnowed feed into bags, and carrying it to the *pie* or the waggon.

"Toward the clofe of the day, when the ftraw has rifen in mountain piles of almoft filver brightnefs; when the field of employment appears on its largeft fcale; when every department is in full work; and when every individual is animated, and not yet fatiated with the entertainments of the day, the rape-thrafhing affords the contemplative mind a pleafing fight, and would afford the pencil a picturefque fubject.

"The two divifions of thrafhers, moving in clofe phalanx, with flails nimbly brandifhing, fometimes in open view, fometimes partially hid among the piles of ftraw; the cloth-men, bufy and attentive to their various employments; the team drawing off the loaded feed; the carriers, from every hand, preffing to the thrafhing-floor, with their feemingly

ingly cumbrous loads, and the distant groups of fillers, scattered on every side of the foreground; could not, he thinks, fail of affording matter interesting to the painter; especially in a country where a suitable offscape is seldom wanting.

"It were almost a pity, says he, that a scene, at once so picturesque and so truly rustic, should sink into oblivion, as in all probability it will, in a short course of years. A more frugal management is growing into esteem, and it is highly probable that, in a few years, public rape-thrashing will be discontinued, and in a few years more be forgotten."

The seed of this sort of crop is, likewise, sometimes cleaned in the field, and put into sacks for the market. But where large quantities of seed are brought quickly together, as they are liable to heat and become mouldy, it may be a better method to spread them out thinly over a barn, granary, or other floor, and turn them as often as necessary. It is stated, that the method of binding crops of this kind in small sheaves, and stacking them in the field, is now much adopted. The barn ought, however, to be preferred.

In respect to the expences of the different operations, such as reaping, turning, thrashing, dressing, and depositing the seed in bags, they may, in general, be estimated at from 30*s.* to 40 or 50*s.* the acre.

The produce is various, according to the difference of culture which the crop has undergone, and the manner in which it has been managed in procuring the seed.

It is further stated by the author of "Modern Agriculture," that cole, on which sheep have been folded, is in many places allowed to stand afterwards to perfect its seed:—A practice which cannot however be recommended, except in cases where it has been slightly eaten off. This is particularly the case, he says, in Northamptonshire, as is evident from the following passage in the report of the present state of agriculture in that district. "Cole, or rape, is cultivated as a spring food for sheep. The sheep are folded in the same manner, as on rye and turnips, and continue till about the end of February. If the winter be favourable, and not very wet, the cole is sometimes allowed to stand for seed, when thirty bushels, on an average, are produced on the acre. In Essex on a medium of the county, Mr. Vancouver states the produce to be twenty-nine bushels the acre. But in the parish of Bradwell, it is set by Mr. Dudley at thirty-four. And at Spaines-Hall, in the largest crops, and best seasons, it rises to five, and even six quarters the acre. Others under these last circumstances have found the produce forty or fifty bushels or more per acre. And Mr. Marshall considers it on the whole, as one of the most profitable crops in farming. On cold unproductive old pasture lands, there have, says he, been instances in which the produce of the rape crop has been equal to the purchase value of the land. The seed is usually disposed of by the last of ten quarters, for the purpose of having oil expressed from it, by mills constructed for the purpose. But it is an article which varies very much in price, as from 18 to 35 *l.* the last. As there are ten quarters, or eighty bushels, in a last, the price of this seed may be said to vary from 4 *s.* 6 *d.* to 8 *s.* 9 *d.* the bushel, according to the prices above mentioned; and from 6 *l.* 15*s.* to 13 *l.* 2*s.* 6*d.* by the acre; average, 9 *l.* 18*s.* 9*d.* Cole, when it thrives, and the seeds are well preserved, is, Mr. Donaldson thinks, one of the most profitable crops known in this country. It is, however, at the same time extremely precarious; being, like turnips, very liable to be destroyed by swarms of flies and insects. And from what has been observed above, it is obvious, that uncommon care and attention are necessary in harvesting this sort of crop. If it be not cut down at the proper time, or if a long continued fall of rain should happen immediately afterwards, the crop is in great danger of being entirely lost.

The great application of this crop is, however, as a green food in the feeding of cattle and sheep. And it has been observed, that where it is to be consumed in this way, the crop will, in general, be sufficiently advanced for the purpose, if there should be a necessity for it, towards the latter end of November; but, except where the seed is to be afterward taken, it is probably a much better practice to reserve it as feed in the spring months. When cut or fed down in the autumn, the plants mostly advance so in the spring as to form a second crop in April. But in this method of feeding off the crop, care should be taken that the plants are not pulled up and destroyed by the animals being confined too long upon them at a time.

In its use for sheep it is scarcely surpassed by any other vegetable, in so far as respects its nutritious properties, and those of being agreeable to the taste of the animals; but in quantity of produce, it is inferior to both turnips and cabbages. In this use, the crops are fed off occasionally, from the beginning of November to the middle of April; being found of great value in the first period, in fattening dry ewes, and all sorts of old sheep, and in the latter, for supporting ewes and lambs. The sheep are folded upon them in the same manner as practised for turnips, in which way they are found to pay from 50 to 60 *s.* the acre, that quantity being sufficient for the support of ten sheep, for ten or twelve weeks, or longer, according to circumstances. And it has been found by experience to be superior to turnips in fattening, and in some cases, even to be apt to destroy them by its fattening quality. In the survey of Lincolnshire, it is likewise stated, that the crop which is grown on fresh land has the stem as brittle as glass, and is superior to every other kind of food in fattening these animals; while in that produced on old tillage, the stem is tough and wiry, and has but little proof in it.

In Essex this crop is also sometimes sown for feeding off with sheep, and also for ploughing in for manuring the land. And other farmers are largely in the system of sowing cole crops to be fed off the same year, for wheat, feeding them off in September for that purpose, by weaned calves, and fattening sheep and lambs, &c. One intention beyond the mere value of the food is that of treading and consolidating the land, as a preventative to the ravages of the wire worms.

As a winter and spring food for sheep, it is therefore almost indispensible. It is evident, however, Mr. Donaldson thinks, that the cultivators of cole, in order to turn the crop to the greatest possible advantage, should always keep in view the double purpose to which it may be applied. By feeding it off slightly with sheep in the early part of winter, the following crop is not materially injured; so that, while a considerable supply of winter food is procured, the return of cole seed by the acre, may not be greatly, if at all diminished: and this, therefore, of all others, seems the most profitable mode of management.

But though for sheep this is a very fattening sort of food, highly productive of milk, and much relished by them; it must be given to cattle with proper caution, as it is apt to hove and burst them in the same manner as clover. When it succeeds, the produce of green feed in the spring is considerable; but where afterwards shut up for seed, the quantity cannot however be expected so large as where it is reserved entirely for that purpose. As a winter and spring food, it is worth from about forty shillings, to three or four pounds per acre, for two or three months in the spring season; for which time, an acre may carry from seven or eight, to ten large sheep, according to circumstances. The haulm of this plant is frequently burned; and in some places the ashes, which are

are equal to pot-aſh, are ſold; by which practice, if no manure be ſubſtituted, the ſoil muſt be greatly deteriorated. It is ſuggeſted by Mr. Marſhall, that the value of the ſtraw to cattle in winter is very conſiderable. The *flover* (pulls and points broken off in threſhing) is as acceptable as hay, and the tops are eaten with an avidity nearly equal to cut ſtraw, better than wheat ſtraw. When well got the ſmaller butts will be eaten up clean. The offal makes excellent litter for the farm yards, and is uſeful for the bottoms of mows, ſtacks, &c. It is a cuſtom, in Lincolnſhire, ſometimes to lay their lands down with cole, under which the ſeeds are found to grow well. But this ſort of crop, as has been already obſerved, is moſt ſuited to freſh broken up, or burned lands, or as a ſucceſſor to early peaſe, or ſuch other green crops as are mowed for ſoiling cattle. The culture of theſe crops for ſeed, has been much objected to by ſome, on account of the great degree of exhauſtion of the land that it is ſuppoſed to produce, but where it is grown on a ſuitable ſoil, and preparation, with proper attention in the after culture; and the ſtraw and offal inſtead of being burnt, as in the common practice, are converted to the purpoſes of feeding and littering cattle; it may, in many inſtances, be the moſt proper and advantageous crop that can be employed by the farmer. This is a kind of plant which is ſometimes alſo known and cultivated under the name of rape. See Rape.

Cole-*Seed*, in *Agriculture*, a name by which the above ſort of crop is ſometimes cultivated, eſpecially when the ſeed is the principal object. See Rape.

Cole-*Fiſh*, more properly Coal-*Fiſh*, in *Ichthyology*, the name by which the gadus carbonarius is known in England. In Cornwall it paſſes under the name of the *Rawlin Pollack*. See Gadus *Carbonarius*.

Cole-*Mouſe*, in *Ornithology*, a ſpecies of *Parus*. See Ater.

Cole-*Pearch*, in *Ichthyology*, a name given to a ſmall fiſh, much eſteemed about Dantzick and other places, for its delicate flavour. It is very like the common river pearch, but it does not grow ſo large, and has a greater variety of colours, and its head is proportionably larger. Phil. Tranſ. N° 83.

Cole-*Seed*, in *Botany*. See Brassica *Napus*.

COLEBROOK, in *Geography*, a townſhip of America, in the northern part of New Hampſhire and Grafton county, ſeated on the eaſt bank of Connecticut river, oppoſite to the Great Monadnock, in Canaan, and ſtate of Vermont; joining Cockburne on the ſouthward and Stuartſtown on the northward; 126 miles W. by N. from Portſmouth.—Alſo, a rough, hilly townſhip on the north line of Connecticut, in Litchfield county; 30 miles N.W. of Hartford city. It was ſettled in 1756. It has two iron-works, and ſeveral mills, on Still river, and N.W. water of Farmington river.

Colebrooke-*Dale*. See Coalbrook-Dale.

COLEFORD, a ſmall town of Glouceſterſhire, England; though poſſeſſing the privilege of a weekly market on Tueſdays, it is only a chapelry to Newland, a village in its vicinity. The original charter for this market was granted by king James I. In the time of the civil wars between king Charles and his parliament, this market-houſe, with ſome other buildings, ſuffered from a ſkirmiſh that took place in this town, when Sir Richard Lawdy, the major-general of South Wales, and ſeveral officers were killed. A new market-houſe was built in 1679, towards the expence of which Charles II. contributed 40*l*; queen Anne gave towards rebuilding the chapel, which had ſuffered at the ſame time, 300*l*. The houſes of this town are ranged moſtly in one wide ſtreet. Coleford is 124 miles N. W. from London. This town is ſituated at the edge of the Foreſt of Dean, within a few miles of the navigable river Wye, and near to the tract of the once propoſed Dean Foreſt Rail-way. See Canal. Rudder's Hiſtory of Glouceſterſhire, 2 vols. folio. Rudge's ditto, 2 vols. 8vo.

COLENDA, in *Ancient Geography*, a town of Spain, which was taken, according to Appian, by Titus Didius after a ſeven months ſiege. It is the preſent *Cavarruvias*.

COLENET, or Colnett *Cape*, a cape on the N.E. coaſt of New Caledonia. N. lat. 20° 30′, E. long. 162° 56′.

COLENETO, in *Geography*, a river of Naples, which runs into the gulf of Tarento, four miles E. of *Roſſano*.

COLENICUI, in *Ornithology*, the name given by Buffon to the *Louſiane* quail, *tetrao Mexicanus*, called alſo Colenicuiltu. Hern.

COLENTUM, in *Ancient Geography*, a town of the iſland of Scardona, on the coaſt of Liburnia, forming part of Illyria.

COLEOPTERA, in *Entomology*, an order of the Linnæan ſyſtem, comprehending ſuch inſects as have four wings, the upper pair of which are cruſtaceous and divided by a ſtraight ſuture. The word is derived from κολεὸς, a *ſheath*, and πτερὸν, a *wing*. See Entomology.

COLERAIN, in *Geography*, a townſhip of America, in the ſtate of Pennſylvania, and county of Lancaſter.—Alſo, a town on the north bank of St. Mary's river, in Camden county, Georgia. By a treaty concluded at this place in 1796, between the United States and the Creek nation of Indians, the line between the white people and the Indians was eſtabliſhed to run from the Currahee mountain to the head or ſource of the main ſouth branch of the Oconee river, called by the white people, Appalatohee, and by the Indians, Tulapocha, and down the middle of the ſame. Liberty was alſo given by the Indians to the preſident of the United States to eſtabliſh a trading or military poſt on the ſouth ſide of Alatamaha, about a mile from Beard's Bluff, or any where from thence down the river, on the lands of the Indians; and the Indians agreed to annex to the ſaid poſt a tract of land five miles ſquare; and in return for this and other tokens of friendſhip on the part of the Indians, the United States ſtipulated to give them goods to the value of 6000 dollars, and to furniſh them with two blackſmiths, with tools.

Coleraine, a townſhip of America in the ſtate of Maſſachuſetts and county of Hampſhire, containing 229 houſes, and 1417 inhabitants.

Coleraine, a market, poſt, and borough town of the county of Londonderry, Ireland, ſituated on the river Bann, about three miles above its mouth. It was anciently a great place of note, being the chief town of a county erected by ſir John Perrot, during his government of Ireland; and on the ſettlement of the preſent county of Londonderry, it gave name to a barony, and had a conſiderable tract of land attached to it under the government of its corporation, called the *Liberty of Coleraine*. It is one of the Iriſh boroughs deemed of ſufficient importance to ſend a repreſentative to the parliament of the United Kingdom. It is of a tolerable ſize, and contains nearly 4000 inhabitants. The port is indifferent, occaſioned by the extreme rapidity of the river, which repels the tide and makes the coming up to the town difficult; yet it has no inconſiderable trade in imports, and it exports ſome butter and hides, beſides large quantities of ſalted ſalmon. In 1801, the average annual duties of this port exceeded 6000*l*., and they have ſince increaſed. There has lately been a conſiderable importation of old drapery, but this will be prevented in future, having been diſcovered to be of a fraudulent nature. Many plans for the improvement of the port and town, by making a canal to the ſea, by opening the navigation of the Bann, and removing the ridge of rocks above the town, have been ſuggeſted, but none of them have been carried into effect. The fine ſalmon fiſheries

 above

above and below the town have engaged the notice of travellers. Mr. Young gives the following account of it. "The salmon ſpawn in all the rivers that run into the Bann about the beginning of Auguſt, and as ſoon as they have done, ſwim to the ſea, where they ſtay till January, when they begin to return to the freſh water, and continue doing it till Auguſt, in which voyage they are taken; the nets are ſet the middle of January, but by act of parliament no nets or weirs can be kept down after the 12th of Auguſt. All the fiſheries on the river Bann let at 6000*l*. a-year. From the ſea to the rock above Coleraine, where the weirs are built, belongs to the London companies; the greateſt part of the reſt to the marquis of Donegal. The eel fiſheries let at 1000*l*. a-year, and the ſalmon fiſheries at Coleraine at 1000*l*. The eels make periodical voyages as the ſalmon, but inſtead of ſpawning in the freſh water, they go to the ſea to ſpawn, and the young fry return againſt the ſtream; to enable them to do which with greater eaſe at the leap, ſtraw ropes are hung in the water for them; when they return to the ſea they are taken: many of them weigh 9 or 10 lbs. The young ſalmon are called *grawls*, and grow at a rate which, I ſhould ſuppoſe, ſcarcely any fiſh, commonly known, equals; for within the year ſome of them will come to 16 and 18 lbs. but in general 10 or 12 lbs.; ſuch as eſcape the firſt year's fiſhery are *ſalmon*, and at two years old will generally weigh from 20 to 25 lbs. This year's fiſhery (1776), has proved the greateſt that ever was known, and they had the largeſt hawl, taking 1452 ſalmon at one drag of one net. I had the pleaſure of ſeeing 370 drawn in at once. They have this year taken 400 tons of fiſh; 200 ſold freſh at $1\frac{1}{2}d.$ a pound, and 200 ſalted at 18*l*. and 20*l*. per ton, which are ſent to London, Spain, and Italy. The fiſhery employs 80 men, and the expences in general are calculated to equal the rent." Mr. Sampſon obſerves, that the fiſh moſt eſteemed are thoſe which weigh from 16 to 20 lbs.; and that the grawls are reckoned one penny a pound inferior to ſalmon. He alſo mentions that the price of ſalmon has riſen to 4*d*. and 5*d*. per lb. principally in conſequence of a communication with the Liverpool market by means of faſt ſailing ſmacks. The linen manufacture is carried on extenſively; and Coleraine gives name to a particular kind of linen made and ſold in this town and the neighbouring ones, which is $\frac{7}{8}$ths wide. Coleraine is 114 Iriſh miles (145 Eng.) N. from Dublin, W. long. from Greenwich 6° 30′, N. lat. 55° 8′. Beaufort, Young, Sampſon, &c.

COLESHILL, a town in Warwickſhire, England, was a royal demeſne, held by Edward the Confeſſor, and William the Conqueror, in whoſe reign, or that of his ſucceſſor, it paſſed to the Clintons, from whom it went to ſir John de Mountfort, in conſequence of his marriage with Joan, daughter of ſir John Clinton, in the year 1353. The manor remained in the family of Mountfort till the reign of Henry VII., when ſir Simon Mountfort, deceived by the pretenſions of Perkin Warbeck, with a belief that he really was the ſon of Edward IV., unfortunately ſent the impoſtor 30*l*. by his youngeſt ſon, Henry; he was ſoon afterwards apprehended, on a charge of aiding Warbeck, tried at Guildhall, London, in 1494, and ſubſequently hanged and quartered at Tyburn. The manor of Coleſhill was immediately granted to Simon Digby, deputy conſtable of the caſtle, who had brought ſir Simon Mountfort to the bar; from him the manor deſcended to the preſent poſſeſſor, the lord Digby. The town is ſituated on a hill of conſiderable height, in the neighbourhood of rich meadows, watered by the Cole, and is adorned by the vicinity of beautiful hanging woods, to which its handſome church and lofty ſpire form a moſt pictureſque addition; the view from the church-yard is equally attractive; but the town includes nothing worthy of notice, except a place neatly built. The church contains many ancient and intereſting monuments, particularly two arches, under which are the effigies of two knights, cruſaders, one of which is aſcertained by Dugdale to have been John de Clinton, who died in 1291. The tomb of Simon Digby, erected by himſelf, previous to his deceaſe in 1519, ſupports the effigies of him and his wife, Alice. This lady left a ſingular bequeſt, of a ſilver penny to every child under nine years of age (whoſe parents were houſekeepers within the pariſh), who ſhould kneel at the altar, every day, after the ſacring of the high maſs, and there ſay five paternoſters, an ave, and a creed, for the ſouls of herſelf, her huſband, and all Chriſtian ſouls. The inhabitants, aware of the ſalutary conſequences to early youth, ariſing from this bequeſt, purchaſed the lands charged with the payment, after they had devolved to the crown by the diſſolution of chantries, part of the rent of which is now diſtributed to thoſe children who attend at church every morning at 10 o'clock, and there ſay the Lord's prayer, and part maintains a ſchool. There are, beſides, handſome tombs to the memory of ſeveral other of the family of Digby, whoſe deſerted ſeat, named Coleſhill-hall, of antique architecture, ſtands in a fine park near the town. About a mile below Coleſhill, is Blithe-hall, ſo termed from its ſite on the river Blithe, once the reſidence of the great and excellent antiquary, ſir William Dugdale, where there are many valuable portraits, but none more ſo than that of ſir William by Boiſcler, painted in 1665.

COLET, John, in *Biography*, well known as the founder of St. Paul's ſchool, London, and one of the revivers of ancient literature in England, was the eldeſt ſon of ſir Henry Colet, knight, an opulent tradeſman, who was twice lord mayor of London. He was born in the pariſh of St. Antholin's in the city, in the year 1466, and although it does not appear at what ſchool he received his elementary inſtruction, or at what college at Oxford he was entered, yet it is certain he ſpent ſeveral years at that univerſity, where he took his degrees in arts in 1490. Afterwards he travelled for improvement in France and Italy, where he reſided about four years. During this period, he diligently cultivated the acquaintance of thoſe perſons, whether foreigners or his own countrymen, who were moſt eminent for literary attainments, and embraced every opportunity of ſtudying the Greek language, which, at this time, was but imperfectly taught in our univerſities; and in which he had made, at home, but a ſlender proficiency. While abroad Mr. Colet employed his time in reading the beſt ancient fathers, and in the ſtudy of eccleſiaſtical hiſtory. Notwithſtanding his abſence, he was preſented at different times to valuable preferments in the church of England, though he had not even taken orders. On his return to his own country in 1497, he received firſt deacon's and afterwards prieſt's orders; and then retired to Oxford, that he might purſue his theological ſtudies without interruption. There he read lectures gratis on St. Paul's epiſtles, and contracted an acquaintance with the learned Eraſmus, which grew into an intimacy and friendſhip of the cloſeſt kind. In his lectures he exhibited much learning; and in his expoſition of the ſcriptures he not only expoſed the corrupt notions of the ſchoolmen, but ſhewed a fearleſs integrity in avowing his own ſentiments. This open and manly conduct procured him a high degree of celebrity, which was followed by new preferments in the church. He was ſucceſſively preſented to a prebend in the church of Sarum; to another in St. Paul's; and, through the favour of the king, was made dean of that church. He introduced the practice of preaching and expounding the ſcriptures, and eſtabliſhed a lecture in St. Paul's church, which is ſuppoſed to have made

made way for the reformation. The freedom of his difcourfes, the reform which he introduced into the cathedral church; the contemptible light in which he held out the conduct of the monaftic orders, and his open enmity to the fuperftitions and corruptions of the church, afforded his enemies an opportunity of accufing him of herefy. He was, however, protected by the archbifhop Warham, and favoured by Henry VIII.; and by their means enabled to triumph over his opponents, and to perfevere in his various undertakings.

About the year 1508, he formed his plan for the foundation of St. Paul's fchool, which he completed in the fpace of four years, and endowed with eftates to a confiderable amount. Here the Greek language was firft publicly taught; and in this excellent inftitution have been educated many of the moft diftinguifhed characters that have adorned our country. The celebrated William Lilly was the firft high mafter in dean Colet's fchool; and the Mercers' company were appointed truftees for the management of this important national concern. This foundation conftitutes an æra in the hiftory of Englifh literature, and merits the grateful regards of every friend to found learning. A few years after he had completed the eftablifhment of the fchool, the dean built a handfome houfe near the palace of Richmond, Surrey, where he meant to retire in old age, that he might receive and enjoy the fociety of his friends. He died, however, before he could realize his intentions, in September, 1519, in the fifty-third year of his age, and was buried on the fouth fide of the choir of St. Paul's; over his grave is a ftone, with the infcription of "John Colet" only: his meritorious deeds fpeak more to his praife than the proudeft monuments of brafs or of ftone. The perfon of dean Colet was tall, handfome, and manly. His manners were conciliating, but his temper was very irafcible; and to obtain a command over himfelf, he practifed much abftemioufnefs, and frequent faftings, befides making ufe of all the motives that religion and philofophy could fuggeft. His attachment to literature was ardent; and his public fpirit can never be forgotten fo long as learning is valued. Though a papift, he was an enemy to the grofs fuperftitions of the church of Rome. He difapproved of auricular confeffion, the celibacy of priefts, and thofe other tenets that have been generally condemned by men of found judgment in every age and country.

By one of his biographers, it is obferved, that "no higher teftimony need be given of the merit of dean Colet, than his great intimacy with Erafmus. There was a fimilitude of manners, of ftudies, and of fentiments in religion, betwixt thefe illuftrious men, who ventured to take off the veil from ignorance and fuperftition, and expofe them to the eyes of the world; and to prepare men's minds for the reformation of religion, and the reftoration of learning. Erafmus, who did him the honour to call him mafter, has given us a hint of his religious fentiments, in his colloquy entitled "Peregrinatio Religionis ergo," in which Colet is the perfon meant, under the name of Gratianus Pullus."

Colet was not diftinguifhed as an author, but we have his "Rudimenta Grammatices:" "The conftruction of the eight parts of fpeech;" and fome religious tracts. He left alfo a convocation fermon in Latin, of which there is a tranflation in the firft volume of the Phœnix, and Epiftolæ ad Erafmum, and other treatifes which ftill exift in manufcript. Biog. Brit. Granger.

COLETON, in *Geography*, a hamlet of King's Ware, in Devonfhire, near to the Froward point at the entrance of the navigable river Dart, (fee CANAL) where there is a naval flag-ftaff, whofe fituation was determined in the Government Trigonometrical Survey in 1795, by an obfervation from Butterton ftation, diftant 87,314 feet, and bearing 75° 0′ 28″ N.W. from the parallel to the meridian of Butterton; and from Furland ftation diftant 8593 feet; whence is deduced its latitude 50° 21′ 2.″3 N. and its longitude 3° 31′ 11″.2, or $14^m\ 4^s.7$ W. of Greenwich.

COLEWORT, in *Botany*. See BRASSICA *Oleracea*.

COLEWORT, in *Agriculture*, a plant of the cabbage kind, which was formerly much more cultivated in the field than at prefent, cabbage plants being fubftituted in its room. It might, however, be a very ufeful plant for feeding milch cows or other cattle, in the fpring, when there is a fcarcity of green food, as it is fo hardy that the froft does not deftroy, or in the leaft injure its growth.

The moft advantageous method of cultivating this plant in the field, is that of fowing the feeds about the beginning of July, choofing a moift feafon, by which the plants may be brought up in about ten or fourteen days. The quantity of feed which is neceffary for an acre of land is generally about nine pounds. When the plants have got five or fix leaves, they fhould be hoed in the fame manner as turnips, cutting down all the weeds from among them; and alfo thinning out the plants where they are too thick; but they fhould be kept thicker than turnips becaufe they are in more danger of being deftroyed by the fly. This work fhould be performed in dry weather, that the weeds may be killed. About fix weeks after this, the plants fhould have a fecond hoeing; which, if carefully performed in dry weather, will entirely deftroy the weeds, and make the ground clean, fo that they will require no farther culture. In the fpring they may either be drawn up, and carried out to feed the cattle, or the beafts may be turned into the field to feed upon them as they ftand; but the former method fhould be preferred, becaufe there will then be little wafte; whereas, when the cattle are turned in among the plants, they tread down and deftroy more than they eat: efpecially when they are not fenced off by hurdles. By fowing the feeds in rich beds of ground, and afterwards removing the plants into the field, in the way that cabbage plants are managed, the produce of this vegetable might perhaps be rendered more abundant. See BRASSICA and CABBAGE.

In the practice of J. C. Curwen, efq. thefe plants have been found highly beneficial as a green food for milch cows; they have alfo been found to anfwer well for fheep in fome [illegible].

COLGIAT, a gantlet, which the Turks carry in war. The colgiat covers the arm down to the elbow, and in defending the hand it at the fame time enables them to parry off the blows directed againft the head.

COLI, GIOVANNI, in *Biography*, an excellent frefco painter, who was born at Lucca in 1634. He purfued his ftudies in company with Filippo Gherardi under Pietro di Cortona, and a friendfhip of fo powerful and lafting a nature took place between the two young artifts, that it could only be diffolved by the hand of death, which carried off Coli in 1681. Until this period they had ever painted together, each heightening his enjoyments and foftening his labour, by fharing them with the other. They were fome years at Venice, where they acquired much of the ftyle of that fchool and painted the ceiling of the library of St. Giorgio Maggiore. Amongft the greateft of their joint works at Rome, are thofe of the grand gallery in the palace Colonna, and of the church of the Lucchefi. Their principal work at Lucca is the Tribuna of the church of St. Martino in frefco, and three altar-pieces in oil, in the church of St. Matteo. Orlandi. Lanzi. Storia Pitt.

COLI *Sonalis, feu Goyolcozque*, of Ray, is the leffer Mexican quail. See TETRAO *coyolcos*.

COLI *valvula*, in *Anatomy*, is a valve formed in the point of of communication between the large and small intestines. See INTESTINE.

COLIACUM *promontorium*, in *Ancient Geography*, a promontory of India, N. of Taprobana, separating two small gulfs: the same which is called by Ptolemy *Cory*, and by others, *Calligiacum*, *Colis* and *Colias*.

COLIAS, a promontory of Attica, on the coast of the Saronic gulf, S.E. of the port of Phalerus. In this place were a temple and statue of Venus, whence Venus was denominated Colias. Here were also statues of goddesses called "Genetyllides," because they presided over childbirth. Suidas reports, that in this place there was a manufacture of vessels painted with vermillion.

COLIART, in *Ichthyology*, the French name of the *Raja batis* of Linnæus, which see.

COLIBERTS, *Coliberti*, in *Law*, were tenants in soccage, and particularly such villeins as were manumitted, or made freemen. Domesday.

But they had not an absolute freedom; for though they were better than servants, yet they had superior lords, to whom they paid certain duties, and in that respect might be called servants, though they were of middle condition between freemen and servants. Du-Cange.

COLIBRI, in *Ornithology*, the general name under which Buffon describes the family of humming-birds (Trochili of Linnæus) which have the beak curved. See TROCHILUS.

COLICA, *Colic*, in *Medicine*, a pain in the abdomen, particularly about the region of the umbilicus, or navel, attended with constipation.

This term was probably originally intended to designate a pain of the large intestine, or *colon*, only. Celsus observes, "Intra ipsa intestina consistunt duo morbi, quorum unus in tenuiore, alter in pleniore est. A plerisque video nunc illum priorem εἰλεὸν, hunc κωλικὸν nominari." (Lib. iv. cap. 13.) In the writings of Hippocrates, the word *colic* is not to be found; it was probably first employed by Celsus. (See Tronchin de Colica pictonum, cap. i.) At present, it is used as a general term, and is applied to a variety of painful affections of the abdomen, which differ considerably in their seat and causes; but which agree in their general character of a deep-seated pain in the belly, occupying more especially the umbilical region, frequently accompanied with nausea, or even vomiting, and generally with a constipation of the bowels. See Cullen. Nosol. Method. Gen. 59. Under circumstances of great aggravation, when the peristaltic motion of the intestines becomes inverted, so that stercoraceous matter is thrown up by vomiting, the denomination of *ileus*, or *iliac passion*, has been applied to this disease by modern authors.

The pain, in colic, is seldom fixed and pungent in any one part of the belly; but is generally a painful distention spreading in some measure over the whole of the abdomen, and particularly with a sense of twisting or wringing round the navel. At the same time the navel and teguments of the belly are frequently drawn inwards, and often the muscles of the belly are spasmodically contracted, and this in separate portions, giving the appearance of a bag full of round balls. The bowels are costive, and the stomach is squeamish, so as frequently to reject the food and drink, which are swallowed; and in these vomitings, not only the contents of the stomach are thrown up, but also the contents of the duodenum, and therefore frequently a quantity of bile. The colic is unaccompanied by fever in the beginning; but if it be not relieved, an inflammation is liable to ensue in the part of the intestine especially affected, which aggravates all the symptoms of the disease. When this takes place, the pain of the abdomen, which in the beginning was moveable, and relieved by external pressure, is greatly aggravated by the same cause, and becomes fixed; and the patient is unable to stand erect; but leans forward, to diminish the tension of the muscles and integuments of the belly. The pulse, which was little altered at the commencement, becomes frequent, small and wiry. The breathing becomes difficult, and the patient is cut off with the symptoms of intestinal inflammation. See ENTERITIS. To this inflammation the vomiting of fæcal matter, which constitutes the ileus, has generally been attributed. Dr. Cullen, however affirms, that, as there are inflammations of the intestines without stercoraceous vomiting, so he has seen instances of stercoraceous vomiting without inflammation; there is therefore no ground for distinguishing ileus from colic, but as a higher degree of the same affection. First Lines of Pract. §. 1438.

The symptoms of colic, and the dissections of bodies dead of this disease, shew very clearly, that it depends upon a spasmodic constriction of a part of the intestines; and that this therefore is to be considered as the proximate cause of the disease. In some of the dissections of persons dead of colic, an introsusception, or inversion of one portion of the intestine within another, has been observed to have taken place.

The colic has been described by many writers as being of different species. Sauvages enumerates twenty, exclusive of several species of ileus, rachialgia, &c. which are also varieties of the same affection. (Nosol. Method. Class. vii. Ord. iv.) These distinctions, however, in a practical view, are of little utility; since in all the different modifications of the disease, the proximate cause appears to be the same, that is, a spasmodic constriction of a part of the intestines; and consequently, in all the instances, the principal indication of cure is the same; namely, to remove that constriction. Even where the disease depends upon a mechanical obstruction of the intestine, as from accumulated forces, calculous concretions, or a thickening and narrowing of the bowel itself, it is not produced by the existence of these obstructions, unless spasmodic constrictions of the intestines are brought on.

The exciting *causes*, which are as various as the modes of irritation which can act upon the bowels, have been assumed as the sources of distinction of the species of colic. Hence the following varieties have been pointed out by nosologists; namely *colica flatulenta*, arising from wind in the bowels, and known by the great discharge of it with the stools, or glysters, by the rumbling noise or borborygmi, and by the frequent change of the seat of the pain;—C. *pituitosa*, from a supposed collection of mucus in the canal;—C. *stercorea*, from hardened fæces lodged in the bowels, occurring generally after long constipation, and in persons of habitually slow bowels; this commonly constitutes the variety of colic which occurs in women in the latter stages of pregnancy, or C. *gravidarum*. Other species have been noted under the titles of C. *verminosa*, arising from the irritation of worms in the intestine, which stimulates it to partial spasmodic constrictions, especially the round-worm or lumbricus;—C. *biliosa*, excited by an unusual secretion of acrid bile, frequently accompanied with a lax belly, and bilious stools;—C. *calculosa*, in which the spasmodic actions are excited by the stimulus of concretions lodged in the bowels, especially in the colon; and under which head also may be included the colic occasioned by hard substances taken in by the mouth, as the stones of plums, cherries, or other such fruit;—C. *accidentalis*, which is of temporary duration, being produced by indigestible aliment, or by too great a quantity of proper food, or by other matters, which by their mechanical, chemical, or some other peculiar quality, irritate the intestines as they pass

paſs through it, and which terminate when thoſe matters are diſcharged. The colica *à frigore* ariſes from the action of external cold, eſpecially when applied to the feet, between the integuments of which and the bowels there is a great ſympathy. The C. *hyſterica* may perhaps be properly included under the C. flatulenta. The C. *meconialis*, and C. *lactentium*, conſtitute the gripings of infants and children, the former ariſing from the retention of the meconium, within the firſt ſix weeks after birth; the latter, after that period, from the prevalence of acidity in the ſtomach and primæ viæ. (Sauvage's Loc. Cit.) Of the C. *pictonum*, ariſing from the poiſon of lead, we ſhall ſpeak more particularly afterwards.

The chief point, both in directing our prognoſis, and our choice of remedies, in colic, is the preſence or abſence of inflammation. The continuance of that irritation, which in the beginning excites a ſpaſmodic action in the muſcular coat of the inteſtines, produces at length an inflammation in the ſame part. Before we proceed to apply our remedies, then, the principal diagnoſis which we muſt determine, is whether the pain is occaſioned by ſimple ſpaſm, or by a ſupervening inflammation. The favourable ſymptoms, which imply the ſpaſmodic ſtate, are a ſoft pulſe, of natural, or of little increaſed frequency; the pain intermitting occaſionally, or moving from one part to another, and being relieved, or at leaſt not increaſed, by external preſſure; and the occurrence of fæculent evacuations. The unfavourable ſymptoms, on the contrary, as leading to a ſuſpicion of inflammation, are a conſiderable duration and unremitting ſeverity of the pain, obſtinate conſtipation, with tenſion of the abdomen, and an aggravation of the pain by preſſure; a very frequent, ſmall, and hard pulſe: the ſkin being hot and dry, or partially moiſt with clammy ſweats; frequent retching, with a dry, brown tongue, hiccup, and delirium.

The principal indications of cure, in colic, are, 1ſt, to prevent or remove inflammation; 2d, to relieve the ſpaſmodic conſtriction and pain of the bowels; and 3d, to excite their regular action, and procure free and fæculent ſtools. The means by which theſe indications muſt be fulfilled, though obvious in general, will be neceſſarily varied by circumſtances, eſpecially by a conſideration of the nature of the exciting cauſe, and of the progreſs and variety of particular ſymptoms.

1. Where inflammatory action has already taken place, as indicated by the ſymptoms before enumerated, eſpecially by the ſeverity of pain, by its increaſe on preſſure, and by the very frequent, hard pulſe, recourſe ſhould be immediately had to the lancet, and a free bleeding from the arm, from a large orifice, ſhould be effected. In perſons of full and ſtrong habits, this operation may require to be repeated, if the pain ſhould not remit, and the pulſe ſhould remain hard and frequent, and if the blood drawn ſhould exhibit, not only the buffy coat, but a conſiderable contraction of the coagulum. In more delicate habits the ſame purpoſe may be accompliſhed by the application of ſeveral leeches to the abdomen, aided by the warm bath, or warm fomentations, or by the application of a bliſter. In ſtrong habits, indeed, if the pain has been of conſiderable duration, inflammation is always much to be apprehended, and a moderate veneſection may be beneficially employed in anticipating its actual attack. In perſons of a weak and lax conſtitution, however, conſiderable caution is requiſite in the uſe of this powerful expedient, unleſs there is a ſtrong ſuſpicion of the abſolute exiſtence of inflammation.

2. The moſt effectual antiſpaſmodic means that can be reſorted to, are the application of heat, whether in a dry or humid form; and the uſe of opium, either by the mouth or the anus. The application of a dry heat is frequently employed with relief. Thus bladders filled with warm water, or bags of ſubſtances which long retain their heat, or living animals, have been uſed for this purpoſe. But the application of heat in combination with moiſture is perhaps generally more efficacious; and moſt of all, when it is applied to nearly the whole of the ſurface of the body, as by immerſion in the warm bath. The frequent inconvenience, however, or impracticability of this, renders it neceſſary to adopt, as a ſubſtitute, the local fomentation of the belly with cloths wrung out of hot water. The fomentation has one advantage, that it may be longer continued; but to procure all the benefits of immerſion it ſhould be applied at the ſame time to the lower extremities. Upon the ſame principle, a filthy expedient, frequently adopted by the older practitioners, was beneficial; namely the application of the omentum, or the warm ſkin, of a newly killed animal.

Practitioners are not altogether agreed as to the propriety of adminiſtering opiates in colic; many have extolled them as highly uſeful, while others have conſidered them as ambiguous, if not dangerous, medicines. As the tendency of opium is to produce coſtiveneſs, by diminiſhing the irritability, and therefore ſuſpending the periſtaltic motion of the bowels; it is ſuppoſed that while it relieves the pain, it muſt render the cauſe of the diſeaſe more obſtinate, and more eſpecially as upon the ſame grounds, it alſo has a tendency to impede the operation of purgatives. But it muſt be obſerved that the great cauſe of the conſtipation in colic, as well as of the pain, is the ſpaſmodic conſtriction of the bowels; and, therefore, it is obvious, that the moſt effectual way of aiding the operation of a purgative, is to remove this conſtriction, and thus to ſuffer the contents of the bowels to paſs freely along. And ſo far, we believe, from finding the action of purgative medicines impeded by the effects of an opiate, in colic, the practitioner has generally the ſatisfaction of ſeeing, that, after an opiate has been taken, a milder purgative will produce the deſired evacuations, which a more active one had previouſly failed to produce. It is, therefore, to be recommended that an opiate be generally given a ſhort time preceding the adminiſtration of a purgative; or, as the operation of a purgative on the inteſtines is neceſſarily ſlower than that of an opiate, which acts immediately upon the nervous ſyſtem, through the medium of the ſtomach, the opiate and purgative may be advantageouſly combined. Perhaps the only caſes, in which the operation of an opiate can be conſidered as hazardous, are thoſe which have been preceded by long coſtiveneſs, ſo that a ſtagnation and induration of fæces in the colon are to be ſuſpected. In ſuch caſes a ſtool ought to be firſt procured, if poſſible, by laxative medicines, aided by the uſe of emollient glyſters injected repeatedly, in order to ſoften the hardened fæces, and facilitate their expulſion. But even in thoſe circumſtances of coſtiveneſs, Dr. Cullen juſtly remarks, when, without inflammation, the violence of the ſpaſm is to be ſuſpected, when vomiting prevents the exhibition of purgatives, and when with all this the pain is extremely urgent, opium is to be employed, not merely as an anodyne, but alſo as an antiſpaſmodic, neceſſary to favour the operation of purgatives; and it may be ſo employed, when, either at the ſame time with the opiate, or not long after it, a purgative can be exhibited; and in all caſes where the colic comes on without any previous coſtiveneſs, and ariſes from cold, from paſſions of the mind, or other cauſes which operate eſpecially on the nervous ſyſtem, opium proves a ſafe and certain remedy. Firſt Lines, § 1445.

3. As

3. As the ſpaſmodic pains of colic are neceſſarily increaſed by the ſtagnant fæces, it is always important to excite the action of the bowels, and to procure free natural ſtools. Therefore, as we have already ſtated, either ſoon after or in conjunction with an opiate, ſome cathartic medicine ſhould be adminiſtered, either by the mouth or in a glyſter, or both. If the conſtipation has been but of ſhort duration, the neutral ſalts will generally be adequate to the purpoſe of procuring evacuations; ſuch as the magneſia vitriolata, for inſtance, or the cryſtals of tartar, which laſt Dr. Cullen recommends. They both have the advantage of being conveniently repeated at ſhort intervals, in ſmall quantities, until the deſired effect is produced; and they are alſo not liable to diſagree with the ſtomach. The caſtor oil, *oleum ricini*, is alſo a mild and tolerably certain purgative, which may be advantageouſly uſed where there is no ſickneſs preſent. If more active means are required, a few grains of calomel, either alone or combined with a ſmall quantity of jalap or rhubarb, may be employed. But the more draſtic cathartics ſhould be avoided, becauſe they are apt to be rejected by the ſtomach; but particularly becauſe, if they do not ſucceed in removing the obſtruction, their great irritating qualities are liable to excite inflammation, or to increaſe it, if it has already commenced.

The diſeaſe, however, is often confined to the colon, or large inteſtine, and therefore remedies may be applied immediately to the part affected, by means of glyſters. Large quantities of warm water, injected by a proper ſyringe, have frequently had the effect of removing the pain and ſpaſmodic ſtricture of the colon, partly by the ſoothing effects of the warmth, and partly by mechanical dilatation. Opium may alſo be adminiſtered in this way, eſpecially in combination with neutral ſalts, in a large glyſter of warm water, with conſiderable advantage. Theſe emollient glyſters act alſo powerfully in aid of laxative medicines taken by the mouth, particularly where the latter is impeded in their operation by a collection of indurated fæces; for while the periſtaltic motion of the bowels is rouſed by the laxatives in the upper part of the canal, the obſtruction is ſoftened, and looſened in the lower part, by the glyſter. A ſolution of aſafœtida may be frequently adminiſtered with advantage, in the form of a glyſter, as it tends both to relieve the pain by its antiſpaſmodic qualities, and alſo to ſtimulate the lower bowel, to evacuation. But where there is very obſtinate conſtipation, no glyſters are generally more efficacious than thoſe made of turpentine, properly ſuſpended in water, by means of mucilage, or the yolk of an egg. As a laſt reſource, injections of tobacco ſmoke, or of an infuſion of tobacco, are uſually employed, and are powerful ſtimulants to the inteſtines. There are ſeveral caſes, however, on record, in which, after every purgative medicine had failed, and the moſt acrid glyſters had proved ineffectual, the action of the bowels has been fully excited by throwing cold water on the lower extremities. Two caſes of this kind may be found in the Medical Tranſactions of the College of Phyſicians, vol. iii., and another in the Edinburgh Medical Eſſays, vol. v. p. 190. See Cold.

Colica *Pictonum*, or *Colic of Poictou*, is a ſpecies of the diſeaſe peculiar in reſpect to the cauſe, from which it originated, in the progreſs of its ſymptoms, and in the paralytic condition of the body, which it leaves behind. This colic is endemial in ſome countries, and has alſo been at times epidemical in others, where it is not commonly prevalent. It firſt received the name of colica pictonum, by which it is now generally deſignated, from Citois, or Citeſius, as he calls himſelf, phyſician to cardinal Richelieu, it having been epidemic in Poictou to a great extent in 1572. See "Diatriba, de novo et populari apud Pictones dolore Colico Bilioſo," in his "Opuſcula Medica," Paris, 1639. It has been likewiſe denominated *colica damnonienſis*, or *Devonſhire colic*, by Huxham and others, ſince it is endemic in that county; and *painters' colic*, becauſe frequently occurring among painters; and alſo *colica ſaturnina*, becauſe it originates, perhaps invariably, from the operation of the poiſon of lead. In the Weſt Indies, where it is alſo endemic, it is called the *dry belly-ache*. Sauvages has conſtituted it a *genus* diſtinct from colic, under the title of rachialgia.

But although Citois firſt diſtinguiſhed the diſeaſe by a peculiar name, it was well known long before his work appeared. It was equally familiar to the people of Picardy, Britanny, and other provinces of France, as well as in Moravia, Sileſia, and many parts of Germany. (See Langius Epiſt. Med. Droëtus Conſil. Nov. de Peſtilentia, cap. 5.—1572.) A colic, which terminated in paralyſis of the limbs, a termination, we believe, with ſir George Baker, peculiar to colica pictonum, had been deſcribed by Paulus Ægineta, (cap. 18) "de reſolutione ex colico morbo oborta;" by Avicenna and ſome other Arabian phyſicians; and by ſeveral continental writers, Fernelius, Hollerius, Foreſtus, &c. as well as by our countryman, John of Gaddeſden, in his "Roſa Anglica," cap. 20, prior to the time of Citois. The reader who is deſirous of obtaining a minute hiſtorical view of the diſeaſe will be amply gratified by the peruſal of the treatiſe of Tronchin, "De Colica Pictonum, Jena 1771," and of the excellent papers of ſir George Baker, in the three volumes of the Medical Tranſactions of the Col. of Phyſicians of London.

The attack of colica pictonum is generally preceded by a ſenſe of weight and uneaſineſs, about the region of the ſtomach or umbilicus, accompanied with ſome languor and diminution of appetite. At length ſlight pains are felt, which remit at times, and are particularly aggravated after eating; theſe in a ſhort time become continued, and extremely ſevere, ſo that the patient lies chiefly on his belly; or rolling about, with expreſſions of the greateſt agony. The eyes become dull, and the complexion pale, and of a dirty or livid colour. The pulſe is often quickened by the ſevere irritation of pain, and the ſkin, though generally cold and damp, is occaſionally rather hot; but there appears to be no tendency in this diſeaſe to inflammation. The ſtomach is in ſome caſes extremely irritable, and rejects whatever is ſwallowed, and the conſtipation is obſtinate. The pain often ſhoots, or is fixed in the back, and the limbs alſo are painful. When theſe ſymptoms occur in painters, plumbers, white-lead manufacturers, poliſhers of glaſs, or perſons of other occupations, in which they are expoſed to the action of the poiſon of lead, there can be no doubt of this ſpecies of colic being preſent. After ſeveral attacks of colica pictonum, a paralyſis commonly affects the fingers, or the whole hand and fore arm, ſo that the former become contracted, and the hands, when the arms are extended horizontally, hang nevertheleſs at a right angle to the arms; the *extenſor* muſcles being in both caſes more paralyſed than the *flexors*.

The exciting *cauſe* of colica pictonum appears to be, in all inſtances, as we have already ſtated, the poiſon of lead. The deleterious powers of this metal, eſpecially in the form of oxyd, or in combination with an acid, have been long well known; nor are they confined to the human ſpecies. Dr. Percival has recorded many examples of the poiſonous effects of lead, when given to hounds, cats, linnets, geeſe, ducks, and other poultry. (Obſervations and Experiments on the Poiſon of Lead.) And its power of exciting colic and paralyſis has alſo been long underſtood: ſince these effects have been frequently traced to the accidental or designed use of the metal, as medicine, or in the food and drink. During the 16th and 17th centuries, when the saturnine salts, especially the acetite of lead, or, as it is vulgarly called, sugar of lead, were administered in large doses medicinally, the colica pictonum and paralysis, in their severest forms, appear to have frequently occurred. Nevertheless, it was not until the investigations of sir George Baker were published, that the poison of lead was suspected even to be the common, much less the exclusive cause of colica pictonum. Such is the difficulty of attaining truth and sound experience in medicine! In those countries where the disease was endemic, it was attributed to a free use of the sub-acid wines, or other such liquors, peculiar to the respective districts, with which, in fact, it was very obviously connected. In the various provinces of France and Germany, where it has been observed to be epidemic in different seasons, it has been clearly observed to prevail among persons who drank freely of those sub-acid fermented liquors, by Sennertus, Spigelius, Cardanus, Citois, and many other writers. The colic of Devonshire is always attributed to the use of the cyder of that county, according to Huxham and Musgrave. The latter briefly remarks, "hanc (scil. colicam) acre facit pomaceum, siquidem eos huic assuetos solum afficit, annis hoc potu divitibus grassatur, pomona negante vix datur." Musgrave de Arthritide Symptomatice. Tronchin De Col. Pict. p. 32. In the West Indies, the endemic colic, called the dry belly-ache, is observed to be the consequence of drinking freely of the newly distilled rum; and this liquor is therefore universally considered as the cause of the disease. But besides these peculiar fermented liquors, and other metallic poisons, as well as lead, authors have assigned several causes to colica pictonum; such are, the remains of imperfectly cured fevers, gout and rheumatism, interrupted perspiration, scurvy, melancholia, and emotions of the mind. See Tronchin. Loc. Cit. To these latter circumstances, however, no one now attributes the origin of colica pictonum. The only doubt which can exist at present, is, whether those sub-acid and spirituous liquors possess any property capable of producing the disease, independently of an impregnation with lead.

It has been remarked, that the cyder of Devonshire produced the colic much more frequently and extensively, than that of other countries, as of Herefordshire; and the wines of some districts on the Continent excited the disease, when similar wines of other districts did not. Sir George Baker ascertained, that a small quantity of lead was employed in several of the mills, in which the apples were bruised for the manufacture of cyder, to fasten the iron cranks, which connected the stone-work. It is well known, too, that in several countries on the continent, the practice of sweetening the wines with litharge, and other preparations of lead, was very common, and that in these districts the colic was particularly prevalent. Dr. Moseley observes, that he was cautioned by Dr. Menghin, of Inspruck, to avoid all sweet wines whatever, but particularly the common tavern wines upon the road, in the Tyrol and in Italy. He adds, that he never deviated from this advice but once, and paid dearly for it at Viterbo. (Treatise on Tropical Diseases, p. 527.) On the other hand, colica pictonum is very prevalent in this metropolis, and other large towns; yet we have never seen an instance, which was not decidedly traced to the operation of lead. A great proportion of house-painters and plumbers, suffer the disease at some period of their life; and a very minute quantity of lead will produce it in some constitutions. Dr. Fothergill has recorded several cases, in which the complaint was occasioned in persons employed in painting with water-colours, who were in the habit of pointing the pencil in the mouth. One of the severest cases which we have witnessed, occurred in a woman, who was occasionally occupied in cleansing polished glass of the remains of the putty, which had been used for the purpose of polishing. It is farther to be added, that in many specimens of cyder, which were analyzed by sir George Baker, a small portion of lead was detected. And in the new rum of the West Indies, which excited the colic throughout some regiments of soldiers, while others were totally free from it, Dr. Hunter discovered, by analysis, the presence of lead. This lead appears to be deposited after a certain time, probably within a year, and the rum loses its noxious quality. See Med. Transact. vol. iii. Sir George Baker. Ibid. Dr. Fothergill Med. Obs. and Inquiries, vol. v. On the whole, therefore, we are satisfied of the correctness of the conclusion of sir George Baker, that colica pictonum is occasioned exclusively by the poison of lead.

The *cure* of colica pictonum must be attempted on the same principles, which we have already laid down for the cure of colic in general; in as much as it consists, like the other species, in a spasmodic constriction of some portion of the intestinal canal. But in this form of colic there appears to be little disposition to inflammatory action; and the doubts and apprehensions, which some practitioners have expressed, of the propriety of administering opiates, until some evacuation from the bowels has been procured, are altogether unsupported by experience. We are satisfied, that, wherever colic can be decidedly traced to the operation of lead, the most effectual, and the only ready cure, is to be found in the administration of a large dose of opium, to be repeated at short intervals, until the pain (and of course the spasmodic stricture) is relieved. When this effect has been produced, there is seldom any difficulty in exciting the action of the bowels, and procuring proper evacuations of fæces; after which, the cure is soon completed by tonics and cordials. This practice of first relieving the pain and constriction by opiates, before the bowels are attempted to be forced by purgative medicines, was strongly recommended by Dr. Warren (Med. Transact. vol. ii.); and was also employed by Dr. Darwin, (Zoonomia, vol. ii.). The practice, therefore, is supported by reason, experience, and authority; and the apprehensions, that opium is liable to excite inflammation in colica pictonum, are altogether hypothetical and gratuitous. As assisting the anti-spasmodic operation of opiates, the warm bath, fomentations, &c. as mentioned under the head of COLIC, may be resorted to with benefit.

For the cure of the palsy, which succeeds to colica pictonum, little can be done by the administration of drugs. The use of the waters of Bath is generally found to be productive of advantage. There seems to be a tendency in the constitution, especially in recent cases, to recover itself, if the exciting cause is avoided, and this may be aided by the local stimulus of warm water, friction, &c. and, above all, perhaps, by mechanical support to the paralyzed hands. Dr. Pemberton has recommended, that, for this purpose, the patient should have his hand and fingers extended upon a sort of battledore, tied to the fore-arm, which should be worn daily. He affirms that, in several instances, a perfect cure of the paralysis from lead has been effected in the course of a few weeks. (Treatise on Dis. of the abdominal Viscera.) It is obvious that the return of colica pictonum, and of the palsy which succeeds it, can only be effectually prevented by relinquishing those avocations, which necessarily expose the patient to the influence of the poisonous metal which excites the disease; or by refraining from those liquors with which any of its preparations are intermixed.

Colica, in *Ancient Geography*, a country of Asia, near mount Caucasus, in the country of the Coraxes. Pliny says that it was a country of Pontus, in which the summits of mount Caucasus directed their course towards the Riphæan mountains.

COLICARIA, a place of Italy, in Cisalpine Gaul, according to the Itinerary of Antonine; 25 miles from Hostilia. M. d'Anville places it W. of Vicus Serninus, and N.E. of Mutina.

COLICÆ Arteriæ, in *Anatomy*, are the arteries which supply the colon. There are generally three of these: the *colica dextra*, which supplies the ascending colon, and the *colica media*, which is distributed to the transverse arch of the intestine, come from the superior mesenteric artery; the *colica sinistra*, which supplies the descending colon, arises from the inferior mesenteric trunk. See Arteries.

COLIC Shell, in *Natural History*, a name given by some to the *porcellana*, or *concha venerea*, from its supposed virtue in curing that disease.

Colic-Stone, the name given by some modern authors to a stone found in New Spain, and some other parts of America, and esteemed of great virtues there in the cure of the colic, and in the diseases of the womb. It is a species of jasper very nearly approaching to the lapis nephriticus, and called by the natives *tlayotic*, and by the Spaniards, *piedra de hyada*. It is of a considerable weight and hardness, and is of a dusky green colour, without any variegations. The Indians cut it into various forms, sometimes of men, sometimes of their idols; sometimes also they figure it into long and even columns, and sometimes into round and flat pieces. All these are nicely polished, and those of the last shape are what are principally used in the cure of the colic. They wet these with their spittle, and then rubbing them, till hot, with their hands, they apply them to the navel in a fit of the colic; and they say, that they immediately carry it off, by determining the humours to pass off, either upwards or downwards, or both ways. They sometimes cut this stone into flat plates also, with two holes cut at each end, by means of which it may be worn, tied to the wrist by a ribband, and it is supposed thus to be a preservative from all diseases of this kind, and from many others.

COLIGNON, François, in *Biography*, an engraver, native of Nancy, who, after he had studied under Callot, and spent some time at Rome, established himself in Paris in 1640, as an engraver and print merchant. His works, which are numerous, consist principally of views of buildings, gardens, and plans of cities, executed in a spirited manner, not unlike that of Israel Silvestre, or Stefano della Bella. Amongst these is a plan of the city of Malta, with the ancient fortifications, and a set of prints representing the buildings erected at Rome under pope Sixtus V. He likewise engraved some prints from Raffaele, the Carracci, Domenichino, and several other masters of the Italian school. Strutt. Heinecken.

COLIGNY, Gaspard de, a character of considerable distinction in the civil wars of France, was born in 1517, and trained to the knowledge of arms at a very early period. Of his youthful exploits nothing is mentioned worthy of historical record. In 1550, he was a colonel-general in the infantry, and employed in forming a pacification between England and France. He was shortly after raised to the post of admiral, and was engaged in many important services for his king and country, in one of which he was taken prisoner by the Spaniards. Upon the death of his royal master, Henry II. he united himself with the Huguenots, and avowed his adherence to the Protestant religion. Excepting the prince of Condé, he was at the head of the party, both in matters of diplomacy and as a soldier. He took up arms against the Guises who had planned the extirpation of the Huguenots, and although in several battles he had the mortification of being obliged to retire from the field, yet his courage and intrepidity never failed him; when wounded, and his friends lamenting over his situation, he observed, that in his profession a man should regard death and life on equal terms. By his talents and bravery the Huguenots, though defeated, were sufficiently formidable to conclude a peace. They had increased so much in numbers, and the progress which their doctrines were still making, was such, that it was imagined they would shortly have become the predominant religion in France. Coligny was invited to the court, and the king, with those about him, used every means of flattery and delusion to throw the admiral off his guard. He suspended his usual prudence, and became reconciled to the chiefs of the party who not long before had offered a large reward to any one who would assassinate him. He who had defied equally the power and menaces of royal authority could not wholly withstand the solicitations of his enemies, who, to answer their own sinister views, had put on the mask of friendship. Inattentive to the presages of his firmest adherents, he refused to leave Paris, and was himself the first victim of the infamous massacre which took place, not only in the capital, but in almost all the provinces on St. Bartholemew's day, 1572. He had, only two days before, been wounded by a hired assassin, named Maurevel, as he was returning from the Louvre, and was on that account confined to his room, when a party, headed by his implacable enemy, the duke of Guise, broke open the door where the admiral was sitting. Besme, one of the duke's domestics, approached him with a drawn sword, "Young man," said the gallant but disabled Coligny, "you ought to respect my age, but act as you please, you can only shorten my life a very few days." The savage pierced his body in many places, and then threw his body into the street, where it was exposed for three days, to the insults of the populace, and then hung by the feet on a gibbet. He was afterwards privately buried in the chapel of Chantilly. Such was the end of admiral Coligny, who, before the commencement of hostilities, was desirous of securing to his party that liberty of conscience in the New World which was denied to them in the Old. Permission was granted him to conduct the Huguenots to the Floridas, and they actually sailed in 1562, but through the mismanagement of those to whom the business was principally entrusted, the project failed, and he was reserved to exhibit in Europe invincible courage as a soldier, great skill and prudence as a politician, and a degree of constancy in his religious principles worthy the cause in which he had embarked, and from the defence of which he never once deviated.

Coligny had two brothers who distinguished themselves in the same cause, and took part in all the principal actions. One of them, Odet, had attained the rank of cardinal in the church, and set the honourable example of quitting his preferment, and uniting himself at the call of conscience to the Protestant interest. He joined his brothers in arms, was married, solemnly deposed, and retired to England, where he was poisoned by a domestic in 1571. Nouv. Dict. Hist. Universal Hist.

Coligny, in *Geography*, a town of France, in the department of the Ain, and chief place of a canton, in the district of Bourg; 12 miles N. of Bourg. The place contains 1658, and the canton 9764 inhabitants: the territory comprehends $177\frac{1}{2}$ kiliometres, and 9 communes.

COLIHAUT, a town on the western side of the island of Dominica.

COLIMA,

COLIMA, a large and rich town of America, in the country of Mexico, and province of Mechoacan, situated in one of the most pleasant and fertile vallies of the country, producing cocoa, cassia, and other valuable commodities, besides some gold; of the breadth of eight leagues, and extending to the sea. Near it is a mountain of the same name, with a volcano, described by Dampier as having two sharp peaks, from which smoke and flame continually issue. A famous plant, called *oleacazan*, is said to grow in the neighbourhood, which is reckoned by the natives a catholicon for restoring decayed strength, and a specific against all sorts of poison. Colima lies 110 miles W. of Mechoacan. N. lat. 19° 50′. W. long. 104° 46′.

COLIMER, a town of France, in the department of the Orne, and district of Mortagne; 4 miles W. of it.

COLIN, a town of Bohemia, in the circle of Caarzim, with a strong castle; 28 miles E. of Prague.

Colin, *grand colin*, in *Ornithology*, the name given by Buffon to the Mexican quail, *tetrao novæ hispaniæ*; which see.

COLINDA, in *Geography*, a town of Hindoostan, in the province of Bengal; 28 miles S. of Comillah.

COLINE'E, a town of France, in the department of the Northern Coasts, and chief place of a canton, in the district of Loudéac. The place contains 465, and the canton 5530 inhabitants: the territory includes 127½ kiliometres, and 6 communes.

COLINIA, in *Ancient Geography*, a name given to the isle of Cyprus.

COLIPHIUM, a name given by Athenæus, and some other authors, to coarse bread made of meal with the bran among it, and such as is eaten by the poorer people in most countries.

The word is derived from κωλον, *a limb*, and ιφι, *strength*, and is a very expressive word, as this sort of bread makes people robust and strong, and is greatly preferable to any other kind for people of strong constitutions, who use hard labour or much exercise. It signifies also a kind of food composed of bread, new cheese, and roasted flesh, which Pythagoras taught the athletæ to use, who before had been used to live on figs.

COLIR, an officer in China, who inspects what passes in every court or tribunal in the empire; and though himself not in the number, yet is assisting at all assemblies, the proceedings whereof are communicated to him.

He is properly what we may call an *inspector*; he gives secret intelligence to the court; and even, on occasion, accuses the mandarins of their faults openly; and that not only of faults in their public offices, but even in private life. To keep him impartial, he is kept independent; by having the post for life. These colirs make even the princes of the blood tremble.

COLIS, in *Ancient Geography*, a country of India, near the sea. The rivers Hypanis and Megarses run towards the confines of this country.

COLISEUM, the name given to the amphitheatre of Vespasian at Rome, either from its magnitude, or from Nero's colossal statue. Under the article Amphitheatre, an account has been already given of its dimensions and contrivance. We have here only to say a few words on its history. It stands upon the spot formerly occupied by a pond enclosed within the walls of Nero's gilded house. The pond being dried up, Flavius Vespasian, A.D. 73, began this celebrated edifice, for public exhibitions, on a plan formed by Augustus, in the then centre of the city. The time which it took in building is not exactly agreed upon by historians; but the greater part appears to have owed its origin to Titus, who employed such of the Jews upon it as were brought in slavery to Rome. When the Goths plundered the city, whatever about the Coliseum was precious, portable, or profane, the statues of the gods and heroes, and the costly ornaments of sculpture, which were cast in brass or overspread with leaves of silver and gold, became the first prey of conquest and avarice. The vacant space, in the centre, was converted into a fair or market; the artisans of the Coliseum are mentioned in an ancient survey; and the chasms, which are still discerned among the massy stones, were either perforated or enlarged to receive the poles that supported the shops or tents of the mechanic trades. (Donatus, Roma Vetus et Nova, p. 285.)

Reduced to its native majesty, says Mr. Gibbon, the Flavian amphitheatre was contemplated with awe and admiration by the pilgrims of the north; and their rude enthusiasm broke forth in a sublime proverbial expression, which is recorded in the eighth century, in the fragments of the venerable Bede. "As long as the Coliseum stands, Rome shall stand; when the Coliseum falls, Rome will fall; and when Rome falls, the world will fall." (Beda in Excerptis seu Collectaneis apud Du-Cange Glossar, med. et infimæ Latinitatis, tom. ii. p. 407. Edit. Basil.) The same learned writer makes mention of a passage in Muratori, from which he gathered, that toward the end of the eleventh or beginning of the twelfth century, during a time of faction, a numerous garrison was lodged in its enclosure.

In 1332, we find a bull-feast celebrated here, after the manner of the Moors and Spaniards. It is described, says Mr. Gibbon, from tradition rather than memory, by Ludovico Buonconte Monaldesco, in the most ancient fragments of Roman Annals, (Muratori Script. Rerum Italicarum, tom. xii. p. 535,536.) and however fanciful they may seem, they are deeply marked with the colours of truth and nature. A convenient order of benches was restored, and a general proclamation, as far as Rimini and Ravenna, invited the nobles to exercise their skill and courage in this perilous adventure. The Roman ladies were marshalled in three squadrons, and seated in three balconies, which, on this day, the third of September, were lined with scarlet cloth. The fair Jaceva di Rovere led the matrons from beyond the Tyber, a pure and native race, who still represent the features and character of antiquity. The remainder of the city was divided as usual between the Colonna and the Ursini; the two factions were proud of the number and beauty of their female bands; the charms of Savella Ursini are mentioned with praise; and the Colonna regretted the absence of the youngest of their house, who had sprained her ancle in the garden of Nero's tower. The lots of the champions were drawn by an old and respectable citizen; and they descended into the *arena*, or pit, to encounter the wild bulls, on foot as it should seem, with a single spear. Amidst the crowd, our annalist has selected the names, colours, and devices of twenty of the most conspicuous knights. Several of the names are the most illustrious of Rome, and the ecclesiastical state; Malatesta, Polenta, Della Valle, Cafarello, Savelli, Capoccio, Conti, Annibaldi, Altieri, Corsi; the colours were adapted to their taste and situation; the devices were expressive of hope or despair, and breathed the spirit of gallantry and arms. The pride or prudence of the Ursini restrained them from the field, which was occupied by three of their hereditary rivals, whose inscriptions denoted the lofty greatness of the Colonna name. The combats were dangerous and bloody. Every champion successively encountered a wild bull; and the victory may be ascribed to the quadrupeds, since no less than eleven were left on the field, with the loss of nine wounded, and eighteen killed on

 the

the ſide of their adverſaries. Some of the nobleſt families might mourn, but the pomp of the funerals, in the churches of St. John Lateran, and St. Maria Maggiore, afforded a ſecond holiday to the people.

This uſe of the amphitheatre, he adds, was a rare, perhaps a ſingular feſtival; the demand for the materials was a daily and continual want, which the citizens could gratify without reſtraint or remorſe. In the fourteenth century, a ſcandalous act of concord ſecured to both factions the privilege of extracting ſtones from it, as a free and common quarry; and Poggius laments that the greater part of theſe ſtones had been burnt to lime by the folly of the Romans. To check this abuſe, and to prevent the nocturnal crimes that might be perpetrated in the vaſt and gloomy receſs, Eugenius IV. ſurrounded it with a wall; and by a charter, long extant, granted both the ground and edifice to the Olivetan Monks. After his death, the wall was overthrown in a tumult of the people; and had they themſelves reſpected the nobleſt monument of their fathers, they might have juſtified the reſolve that it ſhould never be degraded to private property. The inſide was damaged; but in the middle of the ſixteenth century, an æra of taſte and learning, the exterior circumference of one thouſand ſix hundred and twelve feet was ſtill inviolate; a triple elevation of fourſcore arches, which roſe to the height of one hundred and eight feet. Of the preſent ruin, the nephews of Paul III. are the guilty agents; and every traveller who views the Farneſe palace, may curſe the ſacrilege and luxury of theſe upſtart princes. A ſimilar reproach is applied to the Barbarini; and the repetition of injury might be dreaded from every reign, till the Coliſeum was placed under the ſafeguard of religion, by the moſt liberal of the pontiffs, Benedict XIV. who conſecrated a ſpot, which perſecution had ſtained with the blood of ſo many Chriſtian martyrs. (Gibbon's Decline and Fall, vol. vi. p. 635—640.)

Gammucci, Scamozzi, Serlio, Maffei, and ſeveral others occur among the more valuable writers on the Flavian amphitheatre, excluſive of thoſe who have written on the general antiquities of Rome. Some curious particulars alſo may be gathered from "L'Anfiteatro Flavio," "del Cavalier Carlo Fontana," fol. Haia. 1725; and ſome more elaborate details in "Joh. Maranzoni delle Memorie ſacre et profane dell Anfiteatro Flavio di Roma, volgarmente letto il Coloſſe, Diſſertazione," 4to. Rom. 1746. See alſo "Wilkins's deſcription of Ancient and Modern Rome," vol. i. p. 115. and "Tappen's Profeſſional Obſervations on the Architecture of the Ancient and Modern Buildings in France and Italy," p. 151.

The term *Coliſeum* is alſo given to two other amphitheatres; that of the emperor Severus, and the amphitheatre of Capua.

COLISTA, in *Biography*, an eminent performer on the organ at Rome, 1770. He was at this time organiſt of St. John Lateran, the moſt ancient church in Chriſtendom. The organ of this church, which is the largeſt in Rome, was built in 1549, and has undergone two repairs ſince; the one in 1600, by Luca Blaſi Perugino, and a ſecond, a few years ſince, under the direction of the preſent organiſt. It has thirty-ſix ſtops, two ſets of keys, long eighths, an octave below double F. and goes up to E. in altiſſimo. It has likewiſe pedals; in the uſe of which Signor Coliſta is very dextrous. His manner of playing this inſtrument ſeems to be the true organ ſtyle, though his taſte is rather ancient; indeed the organ ſtyle ſeems to be better preſerved throughout Italy than it is with us; as the harpſichord is not ſufficiently cultivated to encroach upon that inſtrument. Signor Coliſta played ſeveral fugues, in which the ſubjects were frequently introduced on the pedals, in a very maſterly manner. But it ſeems as if every virtue in muſic was to border upon ſome vice; for this ſtyle of playing precludes all grace, taſte, and melody; while the light, airy harpſichord kind of playing, deſtroys the *ſoſtenuto* and richneſs of harmony and contrivance of which this divine inſtrument is ſo peculiarly capable.

COLITES, in *Natural Hiſtory*, a name given by ſome writers to a ſtone ſuppoſed to imitate the human *penis*, or *teſtes*, ſeparately, or both together.

COLIUS, in *Ornithology*, the name of the red creeper, β in Moehring's genera of birds, *certhia mexicana* of Gmelin, Trochilus coccineus, Linn. Syſt. nat 6.

Colius, a genus of the paſſerine order, diſtinguiſhed by having the bill ſhort, thick, convex above, and flat beneath; upper mandible bent down at the tip; noſtrils ſmall, ſituated at the baſe of the bill, and nearly covered with feathers; tongue jagged at the tip; tail long and cuneated.

The birds of the colius tribe are moſtly inhabitants of Africa and India. The number of ſpecies at preſent known amount to ſeven, two only of which are deſcribed by Linnæus, the *colius capenſis*, conſidered by that naturaliſt as appertaining to the loxia or croſs-bill tribe, and named by him loxia colius; the other, *colius ſenegalenſis*, which Linnæus claſſes with the butcher birds, under the name of lanius macrourus.

Briſſon firſt propoſed to form a diſtinct genus of thoſe birds under the title of *colius*, which was afterwards adopted by Buffon, under that of *coliou*. The genus *colius*, is inſerted in the Gmelinian edition of the Syſtema Naturæ, and by Dr. Latham in his Index Ornithologicus. Coly is the Engliſh name aſſigned to this genus of birds in the ſynopſis of the laſt-mentioned writer.

Species.

Capensis. Exterior tail feathers white on the outſide; body cinereous, beneath whitiſh. Gmel. Colius capitis bonæ ſpei. Briſſ. Le coliou du cap de B. Eſp. Buff. Vielle, &c. Cape coly. Lath.

This bird inhabits the Cape of Good Hope, and is alſo found in the woods in the ſouthern parts of Africa. Its length is rather more than ten inches; the bill is grey with the tip black; the head and neck purpliſh aſh; breaſt vinaceous; upper tail coverts purpliſh bay; lower coverts, with the belly whitiſh; lower wing-coverts black; legs grey, and armed with black claws.

Senegalensis. Vinaceous-greyiſh; tail blueiſh; head creſted. Gmel. Colius ſenegalenſis criſtatus. Briſſ. Coliou huppé du Senegal. Buff. Senegal Coly. Lath.

According to Latham, this ſpecies is the ſame ſize as the preceding; Gmelin and Vielle deſcribe it as being about the ſame bulk, but meaſuring two inches more in length. As in capenſis the bill is grey with the tip black; the head is decorated with a creſt of long feathers of a ſea green colour, the reſt of the head, neck, breaſt, belly, and lower part of the back grey; wings and tail grey brown; the middle feathers of the tail eight in number, the outer ones ſcarcely an inch in length.

Erythropus. Blueiſh aſh, beneath whitiſh; head creſted; rump purple, with a white ſtreak in the middle; leſs red; all the toes turned forward. Gmel. Le coliou a croupion blanc. Vielle. White-backed coly. Lath.

This bird is a native of the Cape of Good Hope. Its length is twelve inches. The head is ornamented with a creſt ſimilar to that of the Senegal coly; its back is of a cheſnut purple, with a large white band on the lower parr, the reſt of the plumage above is aſh-colour, beneath whitiſh; its legs are yellow with a reddiſh tinge, and the claws are black

black. The fpecies is called by Dr. Latham, colius leuconotos. Ind. Orn.

STRIATUS. Grey; abdomen rufous with tranfverfe black ftreaks; tail green. Colius ftriatus. Gmel. Le coliou rayé. Buff. Radiated coly. Lath.

Rather larger than either of the former fpecies, meafuring in length about thirteen inches; the two middle tail feathers eight inches long. This is an elegant bird, and inhabits the Cape of Good Hope.

PANAYENSIS. Cinereous tinged with yellowifh; beneath rufous; breaft ftriated with black; head crefted. Gmel. Coliou de l'ifle de Panay. Buff. Panayan coly. Lath.

A native of the Ifle of Panay. Size that of the common grofbeak. The feathers on the head are ftraight and very long, and form a creft which the bird can elevate at pleafure. The bill is black; legs pale flefh colour.

VIRIDIS. Shining green; hind head, and eyelids filky black; wings and legs blackifh. Green Coly. Lath. Le Coliou vert. Vielle.

A native of New Holland. The length is twelve inches. The front and bill are black, wings and tail blackifh, the general colour of the plumage fine green.

INDICUS. Cinereous, beneath rufous; hind head, chin, lores, and naked orbits of the eyes yellow. Indian coly. Lath. Le Coliou des Indes. Vielle.

Length fourteen inches. General colour of the plumage cinereous afh above, and reddifh beneath; black, except the bafe, which is red; the legs are red with black claws

COLL, in *Geography*. See COL.

COLLABANG, a town of Hindooftan, in the Malwa country; 44 miles W. of Chandaree.

COLLADO, DIEGO, in *Biography*, a Spanifh Dominican, was born at Eftramadura, at the clofe of the fixteenth century, and ftudied at Salamanca. He went as a miffionary to Japan in 1621, a time when Chriftians were expofed by the natives to every fpecies of perfecution. Meeting with little or no fuccefs, he returned to Rome in 1625, and after fome years he obtained regular permiffion to preach the gofpel in China, Japan, and other eaftern countries. In 1635, he failed with twenty-four of his brethren, and having arrived at the Philippines, he attempted to eftablifh feveral convents, from which miffionaries were to be fent out. This project did not fucceed, and Collado was recalled by the king to Spain; in his voyage home he was fhipwrecked, and loft his life at Manilla. He died in 1638, leaving behind him many works; of thefe the principal are, a "Japonefe Grammar and Dictionary in Latin." "A continuation of Hyacinth Orfanels Hift. Ecclefiaftica Japon." "Dictionarium Linguæ Sinenfis, cum explicatione Latina et Hifpanica, charactere Sinenfi et Latino." Gen. Biog.

COLLAERT, ADRIAN, an engraver and print-feller of Antwerp. He is faid to have received the firft inftructions in his art, in the place of his nativity; after which he repaired to Italy to complete his ftudies. He contributed not a little, by his affiduity, and the facility of his graver, to the numberlefs fets of prints of facred ftories, huntings, landfcapes, flowers, fifh, &c. with which the ftates of Germany and Flanders were at that time inundated. Many of thefe are apparently from his own defigns, and others from Martin de Vos, Theodore Bernard, P. Breughel, John Stradanus, Hans Bol, and other mafters. His ftyle of engraving is at the fame time mafterly and neat, and his knowledge of drawing appears to have been confiderable; but his prints partake of the defects of his contemporaries, with refpect to effect of Chiaro-fcuro; his maffes of light and fhade being too much fcattered, and too equally powerful. The following are amongft his numerous performances. The "life of Chrift in 36 fmall prints." "The twelve months, fmall circles from H. Bol." "The women of Ifrael chanting the pfalm of praife, after the deftruction of the Egyptians in the Red Sea." This artift flourifhed according to Strutt and Heinecken about 1530—1550.

COLLAERT, HANS or JOHN, an excellent draughtfman and engraver, fon to the foregoing artift. He ftudied fome time in Rome, and afterwards fettled in his native place, Antwerp, where he affifted his father in moft of his great works; and afterwards publifhed a prodigious number of prints of his own, nowife inferior to thofe of Adrian. The works attributed by fome to one Herman Coblent, are by Heinecken, fuppofed to be by this mafter. His prints, according to Strutt, are dated from 1555, to 1622, fo that he muft have lived to a great age.

We fhall only notice the following amongft his numerous performances: "the life of St. Francis in 16 prints lengthways, furrounded by grotefque borders." "Time and truth," a fmall upright print beautifully engraved, from J. Stradanus; "the laft Judgment," a large print, encompaffed with fmall ftories of the life of Chrift. M. Heinecken mentions a print by an artift, who figns himfelf William Collaert, and fuppofes him the fon of John Collaert. Strutt. Heinecken.

COLLAR *for Horfes*, from *collier*, Fr. and *collum*, Lat. the *neck*, it being the part to which it is applied. It is not improbable that the ufe of the horfe in draft fervice was prior to that of his being rode, and hence it is reafonable to infer, that the ufe of the collar, or fome fuch apparatus, was nearly coeval with his firft domeftication, or only fecond, perhaps, to the ufe of the pack or pannier, which, as being the moft fimple way of employing the horfe, would firft fuggeft itfelf to his poffeffor.

To any one employing horfes in draft, the conftruction of the collar, and the proper adjuftment of it, cannot be a matter of indifference, as the quantity of force he can exert, and of work which he may be made to perform, will depend in fome degree upon the due application of it, as well as it may ferve, work being made eafy to him, to prolong the period of his fervices.

The collar at prefent in ufe for the lighter kind of draft horfes, may be thus defcribed: it confifts of a frame formed of ftraw, of the exterior figure of the bafe or lower part of the neck; this ftraw is brought together, and firmly bound round by ftrong leather, which is fewed over it; behind this a fofter cufhion or pad is formed, and attached to the former by its leather being reflected over it, and to which it is firmly fewed; as the draft could not be attached to fuch materials, two rods, or ftays of iron, pafs between the collar and pad, having ftaples, loops, or eyes, to which the traces, cords, or chains for draft, are affixed; thefe rods are eafily opened or clofed, and adapted to the fize of the neck by ftraps and buckles at the upper or lower end, or both, the elaftic materials of the collar and pad readily yielding to the figure thefe defcribe; fome of thefe are clofed only by an hinge at the end, and it muft be obvious that they will admit of much variety of ftructure in this refpect; thefe irons are termed the *hames*, probably from carrying the hamus or hook to which the traces are affixed, and on heavy draft horfes they are formed of two ftout pieces of wood, plated with iron, to which the ftaples are affixed, and thefe, as the former, are drawn together or relaxed at either extremity by ftraps or chains, and as they are made to rife confiderably above the withers, it is ufual to place the bearing rein over them, which, in horfes of lighter draft, are carried to the hook of the faddle. All the collars we recollect to have feen, may be reduced to the above general principles of conftruction. This collar fhould not be large enough to get

upon

upon the shoulders, and good room should be left at its lower part for the freedom of breathing.

For cattle employed in husbandry, another description of collar is used, termed the *yoke*, and which is still very much in use in the western parts of England. It appears to be constructed nearly as follows: Two heavy pieces of wood as large as a man's arm, or larger, form an oblong arch, whose sides are nearly upright, and almost parallel to each other; this is placed over the withers of the beast; and through a hole made in the two extremities of this yoke, passes a long stick or rod, which is transversely perforated to receive two pegs, which prevent the yoke from sliding along upon this rod. The two beasts being brought abreast, the same rod is made to pass through both the yokes, and being fastened by the pegs, the cattle are prevented from going from, or coming nearer to, each other; a ring, situated in the middle between the two, and through which the same stick also passes, serves to attach the draft by a chain passing between the two oxen.

This construction has a truly rustic appearance, and, one should suppose, would be but little liable to be out of order. The heavy, and often unnecessary, weight of the yoke has been objected to, as has also the effect of the solid wood resting on the neck or shoulders; and it is becoming more usual to employ collars instead of this; as, however, the head of the ox, from its size, will not admit a collar over it that would fit the neck, it is made, on this account, to open at the top or bottom, and to close after it is on, by a chain or a strap. It is obvious, however, that the complication of traces is prevented by the yoke, and the regularity and evenness of the work are easily seen by the situation of the cross-piece or stick passing straight through the two yokes.

The war-chariot of the ancients appears to have been used with the latter kind of tackling, of which a lucid, useful account has been given us by governor Pownall. (See Berenger's Horsemanship, vol. ii. p. 271.) A pole in this instance passed between the two horses, resting, by its extremity, upon the cross-piece, from the yokes about breast-high; a spike rising from this passed through a perforation in the extremity of the pole, which was then lashed to it firmly by a strong thong of leather; the axletree of the carriage extended the whole width of the two horses, or if four were used, as in the *quadriga*, a pole passed from the *jugum* between each pair of horses, though on some occasions one pole served for the whole four, passing in the middle between them, so that the two outside horses were lashed to the vehicle somewhat in the manner of what, in modern days, are termed outriggers.

The collar in use with them, termed *lepadna*, was a sort of thick, broad, leathern belt, consisting, according to the representations of it on ancient sculptured buildings, to all appearance "of several folds of leather stuck together and bound at the edges, and so cut and shaped as to fit the neck and breast without pressing or pinching in one part more than another when buttoned on;" and upon this sort of collar, if we mistake not, appears to have rested the yoke.

To this apparatus also belonged the *maschalisteris*, or body girth, being a broad leathern belt passing round the chest, and fixed to the *jugum* and the *lepadna* by the *jugalia lora*. This body-girth appears to have been useful principally in stopping and keeping the carriage steady, the yoke in drawing.

The reins passed through the two rings placed on the top of the jugum above the withers.

"The axletrees of these machines were made of extraordinary length, which enabled them to pass in full career over all kinds of ground, over heaps of arms or slaughtered bodies, without the danger of an over-turn."

The body itself of this carriage was simply fixed to the axletree, without being, as in modern times, suspended from it by chains or springs, and then again was fixed to the pole, or *temo*, so that the whole formed one fixed, and, in respect to its parts, immoveable machine.

Of this nature it is evident, from the descriptions of Homer, were those used in the siege of Troy; and of the same kind it is also clear were those in use with the ancient Britons when subdued by Julius Cæsar, and to whom this art appears to have been disclosed, by colonies arriving in Britain, and trading with her from the eastern parts of the Mediterranean. The astonishing monuments of the Druids, who were the priests of these colonies, are also corroborating proofs of this being the actual source of their communication.

To return, however, to the subject of the collar, we may, in concluding this imperfect account, remark, that it is not every servant, having the care of horses, that knows better than that the collar should rest for its principal support against the shoulders, which, however, it ought in no wise to do, or but in a very secondary way, as in such case it would tend to oppress the movements of the shoulder, and the prominent points of bone upon the shoulder-blade, would get rubbed and sore, as there is nothing but skin, covering them; their solid resistance would soon occasion the skin to be worn through, or be much injured and sore, for the place where the collar should rest is not there, but the base of the neck, which in this part is particularly well covered with stout fleshy muscles to a great depth, affording a kind of elastic cushion, that effectually saves the skin from irritation by the pressure or friction of the collar, and which circumstance cannot be too much attended to.

Some horses, it is true, have necks but ill calculated for this kind of harness, being very lean and devoid of muscle, and with such we may often observe the head is unusually large, so much so, that a collar that would fit the neck could not pass over it; in this case the breast-harness must be had recourse to, or a collar opening at the top, as we have already described for the oxen.

In respect to the use of the horses in draft, it might admit of some inquiry to what point of the collar, or rather hames, the draft should be most properly fixed; one should, however, on a first view, be led to imagine, that about the middle of the depth of the collar, or rather below that, would be the most advantageous point for inserting the hook for the draft; in the yoke it would appear that the point of draft was too low, but we do not venture to form an opinion upon a subject we have so little considered, but merely present it as worthy the consideration of those who may be interested in its discussion. Where the horse is much used with the collar in hot weather, or indeed at all seasons, washing the parts pressed upon frequently with cold water hardens them, and prevents the sweat from collecting and injuring the skin.

Collar is an ornament worn by the kings and heralds at arms, judges, chief magistrates, and others; as also by the knights of several orders, hanging over their shoulders on their mantle. Collars usually consist of a chain of gold enamelled, frequently set with cyphers, or other devices, appropriate to the several orders, with the badge suspended at the bottom. The collar of the most noble order of the Garter, weighs 30 ounces troy, is of gold, and contains 26 roses, all within garters, enamelled, and as many knots (in allusion to the sovereign and his companions), from which is pendant the badge, being the figure of St. George on horseback, in armour, encountering a dragon with a tilting spear; and we often find on old monuments and seals, the collar surrounding the arms of of the knight. For the collars of the other orders, fee an account of them under their refpective heads.

COLLAR, in *Roman Antiquity*, a chain fixed round the necks of flaves who had run away, after they were taken, with an infcription, denoting that they were deferters, and requiring them to be reftored to their proper owners.

COLLARS, in *Antiquity*, were not only worn by way of ornament, but alfo as amulets, againft incantations, &c.

COLLAR, *knights of the*, a military order in the republic of Venice, called alfo the order of *St. Mark*, which fee.

COLLAR, *Lord Mayor's*. See CHAIN.

COLLAR *of Brawn*. See BRAWN.

COLLAR, in *Building*. See CINCTURE.

COLLAR *of the plough*, a term ufed in agriculture to exprefs a ring of iron, which is fixed to the middle of the beam, and ferves to receive the ends of two chains, the lower one called the *tow chain*, and the upper one called the *bridle-chain*. The lower chain is fixed at its other end to the box, and the upper, or bridle-chain, to the ftake which runs parallel with the left hand crow-ftaff. Thefe chains, by means of this collar, and their other infertions, ferve to join the head and tail of the plough together. In fome places the bridle-chain is not fixed to the collar, but to the beam itfelf, by means of a pin; and this is the better way on many accounts. See PLOUGH.

COLLAR-*beam*, in *Carpentry*, a piece of timber placed horizontally between the heads of two queen-pofts in a trufs. See ROOF.

COLLAR, in *Ship Building*, the upper part of a ftay; alfo a rope formed into a wreath, by fplicing the ends together with a heart or dead-eye, feized in the bight, to which the ftay is confined at the lower end. There is alfo a collar, or garland, about the main-maft head, which is a rope wound about there, to fave the fhrouds from galling.

COLLARED, or GORGED, in *Heraldry*, fignifies the wearing a collar round the neck of any beaft.

COLLAREDO, in *Geography*, a town of Italy, in the duchy of Tufcany, 4 miles W. of Parana.

COLLARES, or COLARES, a town of Portugal, in the province of Eftramadura, 10 miles N. of Cafcaes.

COLLARINO, GORGERIN, or NECKING, in *Architecture*, that part of a column which is included between the lower fillet of the capital, and the upper aftragal of the fhaft. Thus the collarino is only found in the modern Tufcan order, the Roman, and modern Doric; (See *Plate* XVI. of *Architecture*;) and fometimes, though rarely, in the Ionic order.

COLLATERAL, any thing, place, country, &c. fituate by the fide of another. The word is compounded of *con*, with, and *latus*, fide.

COLLATERAL *arteries of the arm*, in *Anatomy*. Under this general name are included thofe branches, which, arifing from the humeral artery in its courfe along the arm, communicate with the recurrent branches of the arteries in the fore-arm. The profunda humeri major, is called *collateralis magna*; the profunda minor, and one or two other fmall branches, are named *collaterales minores*. See ARTERIES.

COLLATERAL *Points*, in *Cofmography*, the intermediate points, or thofe between the cardinal points. The collateral points are either primary, which are thofe removed by an equal angle on each fide from two cardinal points, or fecondary; which, again, are either thofe of the firft or fecond order. The firft are thofe equally diftant from a cardinal and firft primary; the latter equally diftant from fome cardinal primary, and the firft fecondary.

COLLATERAL *Winds*, are thofe blowing from collateral points. See WIND.

Such are the north-eaft, fouth-eaft, north-weft, fouth-weft, &c. with their fubdivifions.

COLLATERAL, in *Genealogy*, is underftood of thofe relations, which proceed from the fame ftock or anceftor, and in this refpect they agree with thofe that are lineal; but they differ in this refpect, that they do not defcend one from the other. Accordingly, collateral kinfmen are fuch as lineally fpring from one and the fame anceftor, who is the *ftirps*, or root, the *ftipes*, trunk, or common ftock, from whence thefe relations are branched out. Thus, if John Stiles hath two fons, who have each a numerous iffue, both thefe iffues are lineally defcended from John Stiles, as their common anceftor; and they are collateral kinfmen to each other, becaufe they are all defcended from this common anceftor, and all have a portion of his blood in their veins, which denominates them "confanguineous." See CONSANGUINITY.

COLLATERAL *Defcent*. See DESCENT.

COLLATERAL *Affurance*, in *Law*, is a bond, or other fecurity, made over, and beyond the deed itfelf, for the performance of covenants between man and man; thus called, as being external, and without the nature and effence of the covenant. Crompton fays, that to be fubject to the feeding of the king's deer, is collateral to the foil within the foreft. It may be added, that liberty to pitch booths in a fair, or another man's ground, is collateral to the ground.

COLLATERAL *Condition*. See CONDITION.

COLLATERAL *Warranty*. See WARRANTY.

COLLATERAL *Cut*, in *Artificial Navigation*, fignifies the fame with arm or branch of a canal. See CANAL.

COLLATERAL *Bee boxes*, in *Rural Economy*. See HIVE.

COLLATIA, in *Ancient Geography*, a city that ftood on the borders of Latium, and the country of the Sabines, between the Prænestine way and the left bank of the Anio, about fix miles from Rome.

This town was taken by Tarquinius Prifcus, who left in it a garrifon to awe the inhabitants. Tarquinius Collatinus, the hufband of Lucretia, ravifhed by Sextus Tarquinius, was of this town. In Strabo's time it was only a village. M. l'Abbe Chaupy has found its ruins in a place called *Corcollo*.—Alfo, a town of Italy, in Apulia, near mount Garganus, according to Pliny. The inhabitants were denominated Collatini; and the territory Collatinus Ager.

COLLATIO *Bonorum*, in *Law*. See DISTRIBUTION and HOTCHPOT.

COLLATION, in *Canon Law*, the conferring, or beftowing a benefice by a bifhop, who has it in his own gift, or patronage, and this he does, *jure pleno*.

Collation differs from inftitution in this, that the latter is performed by the bifhop, at the motion or prefentation of another; and the former on his own motion.

Befides, by collation, the church is not full; for the higheft patron may at any time remove the collatee, except he hath a right to collate, which plenary by collation may be pleaded; the bifhop's collation, in this refpect, is no more than a temporary provifion for celebration of divine fervice, till the patron prefents.

Collation alfo differs from prefentation, as the latter is properly the act of a patron, offering his clerk to the bifhop to be inftituted into a benefice; whereas the former is the act of the bifhop himfelf. The collator can never confer a benefice on himfelf.

Collation differs from a common prefentation, as it is the giving of the church to the parfon; and prefentation is the giving, or offering of the parfon to the church. But collation fupplies the place of prefentation and inftitution; and

and amounts to the fame as inftitution, where the bifhop is both patron and ordinary. 1 Lil. Abr. 273.

In the Romifh church the pope is the collator of all the benefices, even elective ones, by prevention; fetting afide confiftorial benefices, and thofe in the nomination of lay-patrons. Prelates and bifhops are called ordinaries, or ordinary collectors.

If the ordinary collator neglect to exercife his right for fix months, the fuperior collator may collate by devolution. Thus, if the bifhop neglect, the metropolitan may confer; then the primate; and fo on from degree to degree. In France, the king, according to the old conftitution, was the collator of all the benefices whereof he is patron, excepting confiftorial ones, to which he had only the nomination, and the pope, by virtue of the concordat, was obliged to confer on whomfoever the king nominates. For the reft, he was direct and abfolute collator; and might confer them, by virtue of a kind of priefthood annexed to the royalty.

Other lay-patrons have feldom more than a mere prefentation; the collation properly belonging to the bifhop: yet there are fome abbots who have the full right of collation. The canonifts reckon two kinds of collation; the one free and voluntary, the other neceffary. The firft depending on the mere will of the collator, who may chufe whom he pleafes to fill the vacancy. In the latter, the collator is not at his liberty; which is the cafe where a benefice has been refigned, or changed, and that refignation or permutation allowed of by the fuperior; for here the collator is obliged to grant the provifion to the refignatory, or compermutant.

It is a maxim in the new canon law, *collationes funt in fructibus*; "Thofe who have the fruits of a benefice, have the collation." But in that cafe, the word collation is ufed for prefentation. See LAPSE and PRESENTATION.

COLLATION, in *Common Law*, is the comparifon, or prefentation of a copy to its original, to fee whether or not it be conformable: or the report, or act of the officer who made the comparifon. A collated act is equivalent to an original, provided all the parties concerned were prefent at the collation.

COLLATION is alfo ufed among the Romanifts for the meal or repaft made on a faft-day, in lieu of a fupper.

Only fruits are allowed in a collation: F. Lobineau obferves, that anciently there was not allowed even bread in the collations in lent: nor anything befide a few comfits, and dried herbs, and fruits; which cuftom, he adds, obtained till the year 1513. Cardinal Humbert obferves further, that in the middle of the eleventh century, there were no collations at all allowed in the Latin church in the time of Lent; and that the cuftom of collations was borrowed from the Greeks; who themfelves did not take it up till about the eleventh century.

COLLATION, in *Scots Law*, denotes the right which an heir has of throwing the whole heritable and moveable eftates of the deceafed into one mafs, and fharing it equally with others in the fame degree of kindred, when he thinks fuch fhare will be more than the value of the heritage to which he had an exclufive title.

COLLATION, *collatio*, συμϐολη, in *Rhetoric*, is ufed for COMPARISON.

But Scaliger diftinguifhes, alleging, that in collation, one thing is compared to another that has preceded it; and that the contrary happens in comparifon. That to which any thing is compared is called protafis, and that which is compared is called antapodofis.

COLLATION is alfo popularly ufed for a repaft between dinner and fupper.

The word collation, in this fenfe, Du-Cange derives from *collocutio, conference*; and maintains, that originally collation was only a conference, or converfation on fubjects of piety, held on faft-days in monafteries; but that, by degrees, the cuftom was introduced, of bringing in a few refrefhments; and that by the exceffes to which thofe fober repafts were at length carried, the name of the abufe was retained, but that of the thing loft.

COLLATION *of feals*, denotes one feal fet on the fame label, on the reverfe of ano[illegible].

COLLATIONE *facta uni poft mortem alterius*, in *Law*, a writ directed to the juftices of the Common Pleas, commanding them to iffue their writ to the bifhop, for the admiffion of a clerk, in the place of another prefented by the king, who died during the fuit between the king and the bifhop's clerk: for, judgment once paffed for the king's clerk, and he dying before admittance, the king may beftow his prefentation on another. Reg. Orig. 31.

COLLATIONE *heremitagii*, a writ whereby the king conferred the keeping of an hermitage upon a clerk.

COLLATIONE-*Cut*, denotes a fide arm or branch of a CANAL.

COLLATIONIS *forma*. See CONTRA.

COLLATIVE *Advowfons*. See ADVOWSON.

COLLE, JOHN, in *Biography*, a voluminous writer on medicine, was born at Belluno, in 1558; he ftudied medicines at Padua, under Capivaccius, and was made doctor in that faculty in 1584. At Venice he practifed medicine about fifteen years, when he was promoted to be firft phyfician to the duke of Urbino. In 1591, he was called to fill the chair of profeffor of medicine at Padua, which poft he held with diftinguifhed credit to the time of his death, which happened in 1631.

Among his works are "Medicina Practica, five Methodus cognofcendorum et curandorum omnium affectuum peftilentialium;" containing a hiftory of epidemic difeafes, fol. 1617. In 1610, a fpecies of pleurify prevailed, he fays, which did not bear bleeding in the arm. It was moft fuccefsfully combated by cupping, glyfters, and mild cathartics. "Cofmitor mediceus triplex in quo exercitatio totius artis medicæ decifa, ac confultationes medicinales, et queftiones practicæ enucleatæ proponuntur," Venet. 1621, folio. The book is dedicated to Cofmo the Second, and contains a rational fyftem of medicine, with numerous ufeful practical obfervations. "De morbo gallico, et ejus fymptomatibus," 4to. 1628, contains a brief hiftory of this difeafe. He gave the decoction of the woods, and when they failed he had recourfe to ointments and fumigations, with mercury. For the titles of the remainder of his works, fee Haller's Biblioth. Med. Pract. &c. Eloy Dict. Hift.

COLLE, RAFFAELLO DEL, fo called from the place of his nativity, a fmall town near the city of St. Sepolcro; was a painter of very extraordinary merit, though the circumftance of his chief performances exifting in the environs of the retired fpot where he was born, has occafioned his being but little known. He is faid to have been, in his youth, the difciple of Raffaelle d'Urbino, and to have painted from that great mafter's defigns, the ftories of the Deluge, and the Adoration of the Golden Calf, in the Loggia of the Vatican. After the death of Raff. d'Urbino, he affifted Giulio Romano in many of his great works at Rome, as well as in thofe of the palace of Te at Mantua.

At St. Sepolcro are two altar-pictures by Raffaello del Colle which poffefs great fpirit and beauty, and are worthy of that fchool in which his talents were matured: the firft in the church of S. Rocco, reprefents the refurrection of our Saviour, where the majefty and triumph in the figure of

Christ are finely contrasted by the astonishment and terror of the guards employed to keep watch; the other, in the church of St. Francesco outside the city, describes the assumption of the virgin, and is replete with all the graces of design and colouring. The periods of the birth and death of this master are unknown; we find, however, that he assisted Vasari in the decorations made for the reception of Charles V. at Florence in the year 1536. Langi. Storia Pitt. Orlandi.

COLLE, CHARLES, secretary and reader to the duke of Orleans, was born at Paris in the year 1709. He exhibited an early taste for poetry, and was author of various dramatic pieces. He was also a song writer, and obtained the name of the French Anacreon. For his song written on the capture of Port Mahon, he was rewarded with a pension of 600 livres. He died in 1783, and his works have been collected in 3 vols. 12mo; under the title of "Theatre de Societè:" his verses are neat, and in general well turned, but they are not unfrequently chargeable with indecency. Nouv. Dict. Hist.

COLLE, in *Geography*, a town of Italy, in the duchy of Tuscany, the see of a bishop, suffragan of Florence; 25 miles south of Florence.

COLLE *Dunenzo*, a town of Naples, in the province of Abruzzo Citra; seven miles north of Civita Borella.

COLLE *Duo*, a town of Naples, in the province of Abruzzo Ultra; 23 miles S.W. of Aquila.

COLLE *Salvieta*, a town of the duchy of Tuscany; 10 miles from Pisa.

COLLEAGUE, a companion, partner, or associate in the same office, or magistrature. See ADJUNCT and ASSOCIATE.

The word is particularly used in speaking of the Roman consuls, and emperors.

COLLECHIO, in *Geography*, a town of Italy in the Parmesan; four miles west of Parma.

COLLECT, COLLECTION, a voluntary gathering of money, for some pious or charitable purpose.

Some say, the name *collect*, or *collection*, was used, because those gatherings were anciently made on the days of *collects*, and in *collects*, *i. e.* in assemblies of Christians; but it was more probably, *quia colligebatur pecunia*.

COLLECT is sometimes also used for a tax, or imposition, raised by a prince for any pious design.—Thus histories say, that in 1166, the king of England, coming into Normandy, appointed a collect for the relief of the Holy Land, at the desire, and after the example, of the king of France. See CROISADE.

COLLECT, in the liturgy of the church of England, and the mass of the Romanists, denotes a prayer accommodated to any particular day, occasion, or the like.

In the general, all the prayers in each office are called *collects*; either because the priest speaks in the name of the whole assembly, whose sentiments and desires he sums up by the word *oremus*, *let us pray*, as is observed by pope Innocent III., or because those prayers are offered when the people are assembled together; which is the opinion of Pamelius on Tertullian.

The congregation often is in some ancient authors called *collect* The popes Gelasius and Gregory are said to have been the first who established collects. Despense, a doctor of the faculty of Paris, has an express treatise on collects, their origin, antiquity, authors, &c

COLLECTION, COLLECTIO, in *Logic*, a term used by some for what is commonly called SYLLOGISM, and RATIOCINATION.

COLLECTIVE *Idea*, is a complex idea, which unites many ideas of the same kind under one name, or under one view: as army, dictionary, flock, &c. See COMPLEX and COMPOUNDED *Idea*.

COLLECTIVE, in *Grammar*, a term applied to a word that expresses a multitude; though itself be singular. Thus, troop, company, and army, are nouns *collective*.

COLLECTOR, a person nominated by the commissioners of any duty, the inhabitants of a parish, or the like, to raise or gather any tax, &c. See RECEIVERS.

COLLECTOR, in *Electricity*, is a small appendage to the prime conductor of the electrical machine, generally consisting of pointed wires, affixed to that end of the prime conductor which stands contiguous to the glass globe, or cylinder, or other electric of the machine. Its office is to receive the electricity, whether positive or negative, from the excited electric, much more readily than the blunt end of the prime conductor would be able to receive it without that appendage.

In the simple, or rather defective, construction of electrical machines towards the beginning of the last century, an iron or brass chain, supported in an horizontal position by means of silk strings, formed the prime conductor; and one extremity of that chain hanging perpendicularly down before the globe of glass or sulphur, or other electric, performed the office of collector. Sometimes instead of the chain, a gun barrel, supported horizontally upon silk strings, was used for a prime conductor, and from one end of the barrel a piece of chain came down before the electric, by way of collector. Several years ago, the late sir William Watson, M.D. constructed an electrical machine, in which four glass globes, set one above the other, were excited at the same time. This machine, it seems, is still in existence at the British Museum. A gun barrel formed the prime conductor, and from one end of this barrel a sort of metallic fringe came down and collected the electricity from the four globes, which it touched in the anterior part of their surface. In other machines a sort of tassel of gilt paper formed the collector. But, though this tassel, or chain, or fringe, might answer the purpose sufficiently, at a time when the excitation of the electric was weak, in consequence of the imperfect construction of the machines, small size of the electric, and especially for want of the amalgam, which, since it was introduced by Mr. Canton, has greatly increased the power of the machines; they were in process of time found less useful, and as the science was improved, other methods were adopted; for when the electricity is copiously supplied, those collectors dissipate a great portion of it into the surrounding air, or the adjacent solids; since the dispersion of electricity from the surface of a certain body, seems to be greater than in the simple proportion of the quantity of electricity in that body.

In Dr. Priestley's electrical machine, which he described in his History of Electricity, (part v. sec. ii.) the prime conductor is an hollow copper vessel of a pear-like form, the upper part of which is furnished with a long bent wire in the form of an arch. The farther end of this wire comes near the glass globe, and is formed into a ring, in which are hung some sharp pointed wires, that play lightly upon the surface of the globe when it is in motion. This form of the prime conductor, bent wire, &c. is, however, very improper on various accounts. But with respect to the collector, there is no occasion to place the pointed wires so near as to touch the glass globe or cylinder. In Nairne's patent electrical machine, in which the conductors are placed parallel to the axis of the glass cylinder, a number of pointed wires, little more than an inch in length, are fixed on the side of the conductor, and are situated so as to come with their points within the diftance of about a quarter of an inch from the furface of the glafs cylinder. Indeed pointed wires, fixed immediately on the blunt end of the prime conductor, from about one quarter of an inch to three inches in length, according to the fize and fhape of the machine, and directed towards the glafs globe, or cylinder, or plate, of the electrical machine, fo that their pointed extremities may ftand at the diftance of about half an inch from the glafs furface, form the beft fort of collector; and fuch have been ufed in the beft and moft powerful machines, conftructed by Nairne, Dollond, Adams, Cuthbertfon, Jones, and other eminent philofophical inftrument makers.

In order to afcertain what number of pointed wires would be fufficient to form the collector for any particular electrical machine, feveral experiments were made fome years ago, by a few fcientific gentlemen. They fucceffively placed at the end of the prime conductor, one, two, three, and many more, pointed wires; and with each number examined the length and power of the fpark drawn from the end of the prime conductor; the revolution and excitation of the cylinder being continued as equally as it was poffible. They alfo repeated the fame experiments with machines of various fizes. Upon the whole they found, that a fingle fharp pointed wire between two and three inches in length, imbibed nearly as much electricity from the largeft cylinder, as any number of wires; and two or three wires fet parallel to, and at about one inch diftance from each other, (which in an electrical machine with a very large cylinder acted very little better than a fingle wire) was the utmoft number of wires, that need be ufed for a collector. A greater number, by reaching too far beyond the protection of the blunt end of the conductor, and by coming nearer to the pillars of the machine, ferve only to diffipate the electricity.

The particular fhapes of the collectors for the various forms of electrical machines are exhibited in feveral of the plates belonging to electricity in this Cyclopædia.

Collectors, in *Botany*, fuch ftudents as have attempted the knowledge of plants, without reducing it to any certain fcience, being barely employed about obferving, or getting together the various fpecies. Linnæi Fund. Bot. p. 1.

COLLEDA, in *Geography*, a town of Germany, in the circle of Upper Saxony, and country of Thuringia, 12 miles N. of Weimar, and 16 N.N.E. of Erfurt.

COLLEGATARY, in the *Civil Law*, a perfon to whom is left a legacy in common with one or more other perfons. If the thing be bequeathed *in folido*, the portion of a deceafed collegatary accrues to the reft.

COLLEGE, an affemblage of feveral bodies, or focieties; or even of feveral perfons into one fociety.

College, *collegium*, among the Romans, was ufed for an affemblage of feveral perfons employed in the fame functions, and, as it were, bound together to act, or ferve in concert. The pontifices, augures, feptemviri epulones, and quindecemviri, were called the four colleges of priefts. When divine honours were decreed to Auguftus, after his death, a fifth college was added, compofed of his priefts, hence called "Collegium fodalium Auguftalium." (Tac. Annal. iii. 64. Dio. lvi. 46. lviii. 12.). So "Flavialum collegium" denoted the priefts of Titus and Vefpafian. (Suet. Dom. 4.). To each of the colleges of pontifices, augures, and quindecemviri, Julius Cæfar added one, and to the feptemviri three. (Dio. xlii.). After the battle of Actium, a power was granted to Auguftus, of adding to thefe colleges as many extraordinary members as he thought proper; which power was exercifed by the fucceeding emperors; fo that the number of thefe colleges was from that time very uncertain. (Dio. li. 20. liii. 17.). They feem, however, to have retained their ancient names. But the name of *collegium* was applied not only to fome other fraternities of priefts, befides thofe above enumerated, but to any number of perfons joined in the fame office, as the confuls, prætors, quæftors, and tribunes. Moreover, it ferved indifferently for thofe employed in the offices of religion, of government, the liberal arts, and even mechanical arts, or trades; fo that the word properly fignified what we call a *corporation*, or *company*. In the Roman empire, there were not only the *college of augurs*, and the *college of capitolini*, *i. e.* of thofe who had the fuperintendence of the capitoline games; but alfo colleges of artificers, *collegia artificum*; college of carpenters, *fabricorum*, or *fabrorum tignariorum*; of potters, *figulorum*; of founders, *ærariorum*; the college of lockfmiths, *fabrorum ferrariorum*; of engineers of the army, *tignariorum*; of butchers, *laniorum*; of dendrophori, *dendrophororum*; of centonaries, *centonariorum*; of makers of military cafques, *fagariorum*; of tent-makers, *tabernaculariorum*; of bakers, *piftorum*; of muficians, *tibicinum*, &c.

Plutarch obferves, that it was Numa who firft divided the people into colleges. Finding, upon his acceffion, the city torn to pieces by the two rival factions of Sabines and Romans, he thought it a prudent and politic meafure to fubdivide thefe two into many fmaller ones, by inftituting feparate focieties of every manual trade and profeffion. This he did to the end, that each confulting the interefts of their college, whereby they were divided from the citizens of the other colleges, they might not enter into any general confpiracy againft the public repofe.

Thefe political conftitutions, originally invented by the Romans, were afterwards much confidered by the civil law, in which they were called "univerfitates," as forming one whole out of many individuals; or "collegia," from being gathered together. They were adopted alfo by the canon law, for the maintenance of ecclefiaftical difcipline; and from them our fpiritual corporations are derived. See Corporation.

Colleges were diftinguifhed from other focieties, not formed into colleges by public authority, in this, that thofe who compofed a college, were qualified to treat of the common interefts of their college, which was, as it were, a member of the ftate, and had a common purfe; an agent to negotiate their affairs; fent deputies to the magiftrates when they wanted to treat with them; might make ftatutes and by-laws, for the adminiftration of their college, &c.

There are various colleges on foot among the moderns, built on the model of thofe of the ancients; as the three colleges of the empire, *viz.* the *college of electors*, *college of princes*, and *college of cities*. This diftinction is faid to have been eftablifhed, at the diet of Frankfort, in the year 1580.

College *of Electors*, is the body of electors, or their deputies, affembled in the diet at Ratifbon. The election of emperor is required to be made at Frankfort by the golden bull; though fome emperors have been elected at Ratifbon. See Elector.

College *of Princes*, is the body of princes, or their deputies, at the diet of Ratifbon.

This college of the princes of the empire is more extenfive, as to number, but lefs powerful than the electoral college, which, with the emperor, is at the head of the Germanic body. Thefe princes, as well as the electors, are divided into two claffes, fecular, as dukes, margraves, landgraves, burgraves, counts, &c.; and ecclefiaftic, fuch as archbifhops, bifhops, abbots, &c. that immediately hold of the empire. Thofe who compofe this college, have the

right

right of sitting in the diets, or general assemblies, with a deliberative and decisive voice, and contribute to the necessities of the empire, according to the tax established by the matricular book, or register of the states. The princes of both orders, in the former state of the German empire, held immediately of the emperor and the empire; they had power to appoint judges for the administration of justice, which some of them exercised as sovereigns, while others were limited to certain sums, above which all causes depending must be decided by appeal to the chamber of Spire. They were allowed to establish new laws, create magistrates, grant letters of grace, respite, safe conduct, majority, and legitimation. They had the right to succeed to bastards, to raise and quarter soldiers, erect universities, coin money, make arms, and cast artillery, to increase the number of their fortresses, and secure them with garrisons; make alliances among themselves, as well as with strangers, for their common defence; and, in a word, to reign in their territories as the emperor reigned in the empire. For the change in the German empire that has recently occurred, see CONFEDERATION and GERMANY.

COLLEGE *of Cities*, is, in like manner, the body of deputies which the several imperial and free cities send to the diet. These cities, which were formerly numerous and important, are now reduced to the following six, *viz.* Hamburgh, Augsburg, Lubeck, Nuremburg, Frankfort, and Bremen. The cities of Ratisbon and Wetzlar are no longer considered as imperial, but enjoy an absolute neutrality, even during the wars of the empire, the first as the seat of the diet, and the second as that of the imperial chamber. See CONFEDERATION and GERMANY.

COLLEGE, *Electoral*, in the late organization of the French constitution, denotes a certain class of persons, nominated by the assembly of canton (see CANTON) for each district and department. The electoral colleges of district have a member for every 500 inhabitants domiciliated within the district; but the number of members cannot exceed 200, nor be less than 120. The electoral colleges of departments have a member for every 1000 inhabitants domiciliated within the department; and these members cannot exceed 300, nor be under 200. The members of the electoral colleges are for life. If any member of the electoral college be denounced to government for any act contrary to honour or the interest of the country, the government invites the college to declare its will; but no number under three fourths of the votes shall deprive the denounced member of his place in the college. A place is lost in the electoral colleges for the same causes that deprive a person of the right of citizen. It is also forfeited without any legitimate obstruction, by non-attendance at their successive meetings. The first consul appoints the presidents of electoral colleges for each session; and the president alone has the police of the electoral college, after it is assembled. The electoral colleges appoint for each session two scrutineers and a secretary.

For the purpose of the formation of electoral colleges of departments, there shall be prepared in every department, under the direction of the minister of finance, a list of 600 of the citizens, who stand highest in the rolls of contributions, landed chattel, and sumptuary, and upon the roll of patents. The assembly of canton shall take from this list the members which it is to appoint to the electoral college of the department. The first consul may add to the electoral colleges of districts 10 members, chosen from the citizens belonging to the legion of honour, or who have rendered services. It may also add to every electoral college of department 20 citizens, of whom 10 shall be taken from the 30 of the first consideration in the department; and the 10 others either from the members of the legion of honour, or citizens who have rendered services. He is not confined for these nominations to any fixed period in point of time. The electoral colleges of district present to the first consul two citizens domiciliated within the district for every vacant place in the council of district. One at least of these citizens ought to be necessarily chosen from without the electoral college that presents him. The councils of district are to be renewed, a third at a time, every three years. The electoral colleges of districts present to every meeting two citizens, to form part of the list from which the members of the tribunate are to be chosen: and one at least of these citizens must be chosen from without the electoral college that presents him. Both may be taken from without the department. The electoral colleges of department present to the first consul two domiciliated within the department for every vacant place in the council general of department. One of these, at least, must be taken from without the electoral college that presents him. The councils-general of department are to be renewed by a third every five years. The electoral colleges of department present to every meeting two citizens to form the list from which are to be appointed the members of the senate, one of whom must be taken from without the college that presents him; and both may be taken from without the department. The electoral colleges of department and district present, each of them, two citizens domiciliated within the department, to form the list from which are to be chosen the members of the deputation to the legislative body; one of these must be taken from without the college that presents him. There must be three times as many different candidates upon the list formed by the union of the presentations of the electoral college of department and district, as there are here vacant places. The same person may be a member of a council of commune, and of an electoral college of district or department. A person cannot be at the same time a member of a college of district, and of a college of department. The members of the legislative body and tribunate cannot assist at the sittings of the electoral college, of which they will make part. All the other public functionaries have a right to assist and vote at them. No assembly of canton shall proceed to the nomination of the places belonging to it in an electoral college until these places are reduced to two-thirds. The electoral colleges cannot assemble but by virtue of an act of convocation issued by government, and in the place appointed for them. They cannot occupy themselves with any operations except those for which they are convened, nor continue their sittings beyond the time fixed by the act of convocation. If they exceed these limits, the government has a right to dissolve them. The electoral colleges can neither directly nor indirectly, under any pretext whatever, correspond between themselves. The dissolution of an electoral body operates the renewal of all its members.

COLLEGE *of Cardinals*, or the *sacred college*, is a body composed of the three orders of cardinals, *viz.* cardinal-bishops, cardinal-priests, and cardinal-deacons.

Each order has its dean, or chief. The dean of the cardinal-bishops is always the bishop of Ostia. See CARDINAL.

COLLEGE is also used for a public place, endowed with certain revenues, where the several parts of learning, both divine and human, are taught, in schools, halls, or classes, appointed for that purpose.

An assemblage of several of these colleges constitutes an university.

Among the Greeks, the lyceum and academy were celebrated colleges: the latter of which has given its name to our universities, which in Latin are called *academiæ*. With

 them

them, the houfe or apartment of each philofopher, or rhetor, might be efteemed a kind of college of itfelf. See ACADEMY, and LYCEUM.

The Romans came late into the inftitution of fuch colleges; they had, however, feveral founded by their emperors; efpecially in Gaul; the chief whereof were thofe of Marfeilles, Lyons, Befançon, and Bourdeaux.

The Jews, and Egyptians too, have had their colleges; the chief of the firft were thofe of Jerufalem. Tiberius, Nardea, Pompodita, Sura, and Babylon; the laft is faid to have been inftituted by Ezekiel, and to have fubfifted in the time of Mahomet.

Colleges of this kind have been generally in the hands of thofe confecrated to the offices of religion; the Magi in Perfia, the Gymnofophifts in the Indies, and the Druids in Gaul and Britain, had the care of educating youth in the fciences.

After Chriftianity became eftablifhed, there were almoft as many colleges as monafteries; Charlemagne, in his Capitulars, injoining the monks to inftruct youth in mufic, grammar, and arithmetic; but this calling the monks from their folitude, and taking up too much of their time, the care of the colleges was at length put into the hands of thofe who had nothing elfe to do.

In the canon law, it is faid, three perfons make a college, *tres collegium faciunt.*

The eftablifhment of colleges or univerfities is a remarkable æra in literary hiftory. The fchools in cathedrals and monafteries confined themfelves chiefly to the teaching of grammar. But in colleges, profeffors were appointed to teach all the different parts of fcience. The time that ought to be allotted to the ftudy of each was afcertained. A regular form of trying the proficiency of ftudents was prefcribed; and academical titles and honours were conferred on fuch as acquitted themfelves with approbation. A good account of the nature and origin of thefe is given by Seb. Bacmeifterus "Antiquitates Roftochienfes, five, Hiftoria Urbis et Academiæ Roftoch, ap. Monumenta inedita Rer. Germ, per E. S. de Weftphalen," vol. iii. p. 781. Leipf. 1743. The firft obfcure mention of thefe academical degrees in the univerfity of Paris (from which the other univerfities in Europe have borrowed moft of their cuftoms and inftitutions) occurs A.D. 1215. (Crevier, "Hift. de l'Univ. de Paris," tom. i. p. 296, &c.). They were completely eftablifhed A.D. 1231. It is unneceffary to enumerate the feveral privileges to which bachelors, mafters, and doctors were entitled. One circumftance is fufficient to demonftrate the high degree of eftimation in which they were held. Doctors in the different faculties contended with knights for precedence, and the difpute was terminated in many inftances by advancing the former to the dignity of knighthood, which was accompanied with high prerogatives. It was even afferted, that a doctor had a right to that title without creation. Bartolus taught —"doctorum actualiter regentem in jure civili per decennium effici militem ipfo facto." (Honoré de St. Marie, Differt. p. 165.) This was called "Chevalerie de Lectures," and the perfons advanced to that dignity, "milites clerici." Thefe new eftablifhments for education, together with the extraordinary honours conferred on learned men, greatly increafed the number of fcholars. In the year 1262, there were 10,000 ftudents in the univerfity of Bologna; and it appears from the hiftory of that univerfity, that law was the only fcience taught in it at that time. In the year 1340, there were 30,000 in the univerfity of Oxford. (Speed's Chron. ap. Anderfon's "Chron. Deduction of Commerce." vol. i. p. 172.) In the fame century 10,000 perfons voted on a queftion agitated in the univerfity of Paris, and as graduates alone were admitted to that privilege, the number of ftudents muft have been vaftly great. (Velly's "Hift. de France." tom. xi. p. 147.) There were, indeed, few univerfities in Europe at that time; but fuch a number of ftudents may neverthelefs be produced as a proof of the extraordinary ardour with which men turned to the ftudy of fcience in thofe ages. It fhews likewife that they began to confider other profeffions befides that of a foldier as honourable and ufeful. See Robertfon's Hift. Ch. V. vol. i. p. 389, &c.

For an account of the colleges of Cambridge and Oxford; fee thefe articles. For thofe of Scotland, fee ABERDEEN, ST. ANDREW'S, EDINBURGH, and GLASGOW. For thofe of Ireland, fee DUBLIN and IRELAND.

In America they have alfo many colleges. The moft ancient, as well as the principal, literary eftablifhment in this country is Harvard college, or univerfity, which was founded at Newtown, fince called Cambridge, in the province of Maffachufetts, in the year 1638. It derives its name from the Rev. John Harvard of Charleftown, who left a legacy of 779*l.* 17*s.* 2*d.* fterling, being one half of his eftate, to the further endowment of it. In 1650, this college received its firft charter from the court, appointing a corporation confifting of feven perfons, *viz.* a prefident, five fellows, and a treafurer, to have perpetual fucceffion by election to their offices, under the title of "The Prefident and Fellows of Harvard College." After the declaration of the independence of the United States, the fore-mentioned charter was eftablifhed by the conftitution of Maffachufetts; and the governor and lieutenant governor for the time being, together with the council and fenate of the commonwealth, the prefident for the time being, and the congregational minifters of the following fix towns, *viz.* Cambridge, Watertown, Charleftown, Bofton, Roxbury, and Dorchefter, were declared fucceffors of the old board of overfeers, who had been appointed for its fuperintendence in the year 1642. The executive government confifts of the prefident, three profeffors, four tutors, and the librarian, who fuperintend the morals of the ftudents and the obfervance of the ftanding laws, and make difcretionary regulations in cafes not provided for by the laws. The profeffors and tutors give inftruction in the univerfity. It has a profeffor of divinity, a profeffor of mathematics and natural philofophy, and a profeffor of Hebrew and other Oriental languages, who is alfo profeffor of the Englifh language. The two firft of thefe profefforfhips were founded by Mr. Thomas Hollis of London, merchant, who, together with others of his family, furnifhed the college with the philofophical apparatus, and a number of valuable books; the divinity profefforfhip in 1722; the mathematical profefforfhip in 1726; the profefforfhip of Hebrew, &c. by the Hon. Thomas Hancock, efq. in 1765. Thefe feveral profefforfhips bear the names of their founders. Foundations are laid for two other profefforfhips, *viz.* one of rhetoric and oratory, and another of natural religion, moral philofophy, and civil polity, by the legacies of Nicolas Boylfton, efq. of Bofton; and the Hon. John Alford, efq. of Charleftown. In 1782 a medical inftitution was formed in the univerfity. It confifts of three profefforfhips, *viz.* one of anatomy and furgery, one of the theory and practice of phyfic, and another of chemiftry and the materia medica. Among the prefidents and profeffors of this univerfity, we find feveral perfons eminently diftinguifhed both by natural abilities and acquired accomplifhments. The ftudents are annually examined in the feveral branches of education as far as their courfe has been completed, before a com-

mittee

mittee of the corporation and overſeers. The courſe of education is completed in the univerſity in four years, at the end of which term, thoſe ſtudents, who have complied with other requiſites, are candidates for the degree of bachelor of arts, which is conferred after the public performance of appointed literary exerciſes; and at the end of three years from the time of their receiving this degree, they may be admitted to that of maſter of arts, if there be no legal impediment. All academical degrees are publicly conferred by the preſident, on the commencement day, which is the third Wedneſday in July, annually. This, it is ſaid, is one of the moſt ſplendid anniverſaries in the United States. From the eſtabliſhment of this college to the year 1794, 3399 young perſons received its honours, of whom 1079 became miniſters of the goſpel. This moſt ancient of all the American literary inſtitutions has furniſhed, both for the church and ſtate, its full proportion of eminently learned and uſeful men. The college poſſeſſes ſome funds, ariſing from the eſtate of Edward Hopkins, eſq. of Great Britain, for the ſupport of graduates, and alſo from a legacy of 400*l.*, bequeathed by governor Bowdoin, for the encouragement of reſident graduates and under-graduates. The public buildings belonging to the univerſity are Harvard hall, appropriated to public rooms, ſuch as a chapel, a dining-room, library, philoſophy chamber, an apartment for the philoſophical apparatus, which is reſpectable, though deficient in aſtronomical inſtruments, Hollis hall and Maſſachuſetts hall, which contain private rooms, and are occupied by the tutors and ſtudents, and Holden chapel, now occupied by ſome of the medical profeſſors. The ſum of 8000*l.* was raiſed by a lottery in 1794, towards erecting another hall, for the accommodation of ſtudents. The library conſiſts, as we are informed, of about 13,000 well-ſelected and valuable books, the number of which is increaſing by donations, and by the income of a legacy, bequeathed by the late Thomas Hollis, eſq. of London. The muſeum of the univerſity, which has been indebted to the munificence of Dr. Lettſom of London in 1794, and to that of the French Republic in the following year, is furniſhed with a handſome collection of natural and artificial curioſities. The colleges are ſituated in a pleaſant and healthful part of Cambridge. Their diſtance from the centre of Boſton is eight miles by the way of Roxbury, 4½ miles over Charles river bridge, and 3½ miles over Weſt Boſton bridge. The latitude of Harvard hall, determined by obſervations, is 42° 23′ 28″, and W. longitude from Greenwich 4^h 44^m 30ˢ in time, or 71° 7′ 30″.

An academy in Williamſtown, in Berkſhire county, founded and endowed ſeveral years ſince by Col. Ephraim Williams, and in 1790 provided with a brick edifice, containing 24 rooms for ſtudents, a large ſchool-room, a dining-hall, and a room for public ſpeaking, was erected in 1793 into a college by an act of the legiſlature, under the name of "Williams' College," in honour of its liberal founder.

The general aſſembly of the ſtate granted a charter in 1764, for founding a college under the name of "The Truſtees and Fellows of the College or Univerſity, in the Engliſh colony of Rhode iſland and Providence plantations." The number of truſtees is 36, of whom 22 are of the Baptiſt denomination, 5 of the denomination of Friends, 5 Epiſcopalians, and 4 Congregationaliſts. The preſident muſt be a Baptiſt; the profeſſors and other officers for inſtruction are not reſtricted to any particular denomination. This inſtitution was firſt founded at Warren, in the county of Briſtol; but removed in 1770 to Providence, where an elegant building was erected for its accommodation. It has 48 rooms for ſtudents, and 8 of a larger ſize for public uſe. This inſtitution is under the inſtruction of a preſident, a profeſſor of divinity, a profeſſor of natural and experimental philoſophy, a profeſſor of mathematics and aſtronomy, a profeſſor of natural hiſtory, and three tutors. It has a library of between two and three thouſand volumes, and a valuable philoſophical apparatus. The funds of the college, at intereſt in the treaſury of the ſtate, amount to about 2000*l.*

Yale college, in the ſtate of Connecticut, was founded in 1700; and remained at Killingworth until the year 1707; then at Saybrook until 1716, when it was removed to New-Haven, where it was fixed. Governor Yale was one of its principal benefactors, and in honour of him it was named, in 1718, "Yale College." Its building furniſhes chambers for lodging 120 ſtudents, a chapel, a dining-hall, a houſe for the preſident, and another for the profeſſor of divinity. Its library conſiſts of about 3000 volumes, and it is provided with a competent philoſophical apparatus. The college muſeum is a repoſitory of many natural curioſities. The firſt charter of incorporation was granted by the general aſſembly of Connecticut in 1701; renewed in 1723; and in 1745, the truſtees were incorporated by the name of "The Preſident and Fellows of Yale college, New-Haven." And by an act of the general aſſembly, paſſed in 1792, the governor, lieutenant-governor, and the ſix ſenior aſſiſtants in the council of ſtate, are appointed to be for ever, by virtue of their offices, truſtees and fellows of the college, in addition to the former corporation. The corporation is empowered to make laws, to hold eſtates, to continue their ſucceſſion, to elect and conſtitute all officers for inſtruction and government, and to confer all the learned degrees. The immediate executive government is in the hands of the preſident, profeſſors, and tutors. The preſent officers and inſtructors of the college are, a preſident, a profeſſor of divinity, and a profeſſor of natural philoſophy and aſtronomy, and three tutors. The number of ſtudents, at an average, is about 150, divided into four claſſes. The funds of the college, before the liberal addition made by a grant of the general aſſembly in 1792, conſiſted of rents of lands to the amount of 800*l.* a year, about 800*l.* raiſed by fees of the ſtudents for tuition, beſides funds for the ſupport of two profeſſorſhips. The ſeveral claſſes are examined twice in the year; and a public commencement is held annually on the 2d Wedneſday in September. From the year 1700 to 1793, there had been educated and graduated at this univerſity about 2303 perſons; about 800 of whom had been ordained to the work of the miniſtry.

King's college, in the city of New York, was principally founded by the voluntary contributions of the inhabitants of the province, aſſiſted by the general aſſembly and the corporation of Trinity church; and in 1754, a royal charter and grant of money being obtained, a number of gentlemen were incorporated by the name of "The governors of the college of the province of New York, in the city of New York, in America;" which charter granted various privileges, and among others, that of conferring all ſuch degrees as are uſually conferred by the Engliſh univerſities. The charter provides, that the preſident ſhall be always a member of the church of England; but at the ſame time, no teſt of their religious perſuaſion was required from any of the fellows, profeſſors, or tutors; and the advantages of education were equally extended to ſtudents of all denominations. The building is an elegant ſtone edifice, with four ſtair-caſes, having in each 12 apartments, and containing alſo a chapel, hall, library, muſeum, anatomical theatre, and a ſchool for experimental philoſophy. Since the revolution,

the

the legislature has passed an act, constituting 12 gentlemen, the governor and lieutenant-governor always included "ex officiis," a body corporate and politic, by the name of "The Regents of the University of the State of New York." This body has powers to grant charters of incorporation for erecting colleges and academies through the state, to visit them whenever they think proper, and to make a report of their state to the legislature once a year. King's college is now called "Columbia College;" and by an act passed in 1787, it was put under the care of 24 gentlemen, who are a body corporate by the name of "The Trustees of Columbia college, in the city of New York." They possess all the powers vested in the governors of King's college before the revolution, or in the regents of the university, since the revolution. The regents of the university have power to confer the higher degrees, and them only. The annual revenue arising from the estate belonging to the college amounts to 1,535 *l.* currency. Columbia college consists of two faculties; one of arts and another of physic. The first has a president and seven professors; and the second a dean and seven professors. The students attending both the faculties in 1795, amounted to 140. The officers for instruction and government in the faculty of each, are a president, a professor of mathematics and natural philosophy, a professor of logic and geography, and a professor of languages. To these have been lately added a professor of chemistry and agriculture, a professor of oriental languages, a professor of law, and a professor of the French language. In the faculty of physic, the dean is lecturer on clinical medicine in the New York hospital, and there are the professorships of botany, of anatomy, of the obstetric art, of materia medica, of the institutes of medicine, of surgery, and the practice of physic. The library and museum were destroyed during the war. Upwards of 800 *l.* granted by the legislature, has been expended in books for augmenting the library. The philosophical apparatus is new and complete.

Another college by the name of "Union college, in the town of Shenectady in the state of New York," was incorporated by the regents of the university in 1794.

In New Jersey there are two colleges, one at Princetown, called Nassau hall; the other at Brunswick, called Queen's college. The former was first founded by charter about the year 1738, and enlarged in 1747. The charter delegates a power of granting "to students of the said college, or to any others thought worthy of them, all such degrees as are granted in either of our universities, or any other college in Great Britain." It has 23 trustees, the governor of the state, and the president of the college, are, "ex officiis," two of them. The establishment in 1796, consisted of a president, who is also professor of moral philosophy, theology, natural and revealed, history, and eloquence; two professors, one of mathematics and natural philosophy, including astronomy, and another of chemistry, considered not only in its relation to medicine, but to agriculture and manufactures; and a grammar master. In the winter session there are generally from 70 to 80 students in the four classes of the college; and in summer from 80 to 90. The present annual income of the college is by fees of the students, and otherwise, about 1000 *l.*; and it has also funds in possession. The library of the college was almost wholly destroyed by the late war; but it has collected, by means of donations, and out of the wreck of the former library, about 2,300 volumes. Its philosophical apparatus, worth about 500 *l.* was destroyed in the war. The college edifice is a handsome stone building, containing 42 chambers, for the accommodation of students, a dining-hall, chapel, and room for the library. Its situation is singularly pleasant and healthful. This college has furnished a number of civilians, divines, and physicians, of the first rank in America. The charter for Queen's college, at Brunswick, was granted just before the war, in consequence of an application from a body of the Dutch church. Its funds, raised wholly by free donations, amounted, soon after its establishment, to 4000 *l.*; but they were considerably diminished by the war. This college at present exists only in name.

The university of Pennsylvania, founded and endowed by the legislature during the war, was lately united with the college of Philadelphia. This college was founded by charter about 50 years ago. In the western part of this state, at Carlisle, is Dickinson college, founded in 1783, and named after his excellency John Dickinson, author of the "Pennsylvania Farmer's Letters," and formerly president of the supreme executive council of this state. It has a principal, three professors, a philosophical apparatus, a library, consisting of nearly 3000 volumes; 4000 *l.* in funded certificates, and 10,000 acres of land, the last, the donation of the state. In 1787, the number of students in this college amounted to 80; and it has since increased every year. In 1787, a college was founded at Lancaster, and honoured with the name of Franklin college, after Dr. Franklin. This college is designed for the Germans, in which they may educate their youth in their own language, and in conformity to their own habits; the English language, however, is taught in it. Its endowments are nearly the same with those of Dickinson college. Its trustees consist of Lutherans, Presbyterians, and Calvinists, German and English, of each an equal number. The principal is a Lutheran, and the vice-principal a Calvinist.

In 1782, a college was instituted at Chestertown, in that county, in the state of Maryland, and honoured with the name of Washington college, after president Washington. It is under the management of 24 visitors, or governors, with power to supply vacancies, and hold estates, whose yearly value shall not exceed 6000 *l.* current money. By a law, enacted in 1787, a permanent fund was granted to this institution, of 1250 *l.* a year, currency, out of the monies arising from marriage licenses, fines, and forfeitures on the eastern shore.

St. John's college was instituted in 1784, under the care of 24 trustees, empowered to fill up vacancies, and to receive an annual income of 9000 *l.* A permanent fund is assigned this college, of 1750 *l.* a year, out of the monies arising from marriage licences, ordinary licences, fines, and forfeitures on the western shore. This college is established at Annapolis. The two colleges constitute one university, by the name of "the university of Maryland," whereof the governor of the state for the time being, is chancellor, and the principal of one of them vice-chancellor, either by seniority or by election. The chancellor is empowered to call a meeting of the trustees, under certain circumstances, which meeting is styled "the convocation of the university of Maryland," who are to frame the laws, preserve uniformity of manners and literature in the colleges, confer the higher degrees, determine appeals, &c.

The Roman catholics have also erected a college at George-town, on Potomak river, for the promotion of general literature. In 1785, the methodists instituted a college at Abington, in Hartford county, by the name of Cokesbury college, after the name of Thomas Coke, and Francis Asbury, bishops of the methodist episcopal church. The students are to consist of the sons of travelling preachers, the sons of annual subscribers, the sons of the members of the methodist society, and orphans, and are to be instructed in English, Latin, Greek, logic, rhetoric, history, geography, natural philosophy, and astronomy; and when the finances of the college will admit, they are to be taught the Hebrew, French, and German languages. This college was erected, and is supported wholly by subscription and voluntary donations.

The college of William and Mary, in the state of Virginia, was founded in the time of king William and queen Mary, who granted to it 20,000 acres of land, and a penny per pound duty on certain tobaccos exported from Virginia and Maryland, which had been levied by the statute of 25 Car. II. The assembly also gave it, by temporary laws, a duty on liquors imported, and skins and furs exported. From these resources it received upwards of 3000 *l.* The buildings are of brick, and sufficient for the accommodation of about 100 students. By its charter, it was to be governed by 20 visitors, and to have a president and six professors, who were incorporated under this charter; a professorship of the Greek and Latin languages, a professorship of mathematics, one of moral philosophy, and two of divinity, were established. To these were annexed, for a sixth professorship, a considerable donation by Mr. Boyle of England, for the instruction of the Indians, and their conversion to Christianity. This was called the professorship of Brafferton, from an English estate purchased with the monies given. There are now six professorships, one of moral philosophy, natural philosophy, and the belles lettres, one of mathematics, one of law, one of modern languages, and two of humanity. The philosophical apparatus is complete, and the library extensive.

The academy, in Prince Edward county, has been erected into a college, by the name of "Hampden Sydney college."

The legislature of Virginia, while Kentucky belonged to that state, made provision for a college in it, and endowed it with very considerable landed funds. A library was also formed for its use. This college has not flourished of late; another has been established, and considerable funds collected for its support.

The general assembly in North Carolina passed a law in 1789, incorporating 40 gentlemen, five from each district, as trustees of the university of N. Carolina. To this university they gave, by a subsequent law, all the debts due to the state, from sheriffs or other holders of public money, and which had been due before the year 1783. They also gave it all escheated property within the state. A considerable quantity of land has also been given to the university. The trustees have fixed on Chapel hill, in Orange county, for the site of the university. The buildings in this elevated and agreeable situation have been completed, and the academical studies commenced in January, 1795.

In the state of Tennessee they have now three colleges established by law, *viz.* Greenville college in Greene county, between Greenville and Nolychuckey river, instituted by act of assembly in 1794, and placed under the management of a president, who has collected, in money and books for its foundation, about 5000 dollars, and 14 trustees. They have also Blount college, at Nashville, and Washington college in the county of the same name.

Three colleges have lately been incorporated by law in South Carolina; one at Charleston, one at Winnsborough, in the district of Camden, and the other at Cambridge, in the district of Ninety-six.

In the state of Georgia, the charter containing their present system of education, supported with funds arising from about 50,000 acres of land, was passed in the year 1785; in consequence of which, a college, with ample and liberal endowments, was instituted in 1801 at Louisville, a high and healthy part of the country, near the centre of the state. The funds originally designed to support the literary orphan-house, founded by the Rev. George Whitefield, have been vested by the legislature, in 1792, on the demise of the countess of Huntingdon, to whom Mr. Whitefield beqeathed this property as trustee, in 13 commissioners, with independent powers, for carrying on the original intention of Mr. Whitefield into execution; and, in compliment to the countess, the seminary is called Huntingdon college.

In 1791, the legislature of the state of Vermont passed an act for establishing an university at Burlington, on lake Champlain, in a delightful situation, on the south side of the Winouski, or Onion river, and appointed 10 trustees. The sum of 6000*l.* was secured by donation, part of which is to be applied to the erection of buildings, and part settled as a fund for the support of the institution. In the several grants made by this state, about 33,000 acres of land have been reserved for the use of this university.

Dartmouth college, so called after the right honourable William, earl of Dartmouth, one of its principal benefactors, is situated in the township of Hanover, and state of New Hampshire, on a beautiful plain, about half a mile E. of Connecticut river, in N. lat. 43° 33′. It was founded by Dr. Wheelock in 1769, who obtained for it a royal charter, with a view of civilizing and christianizing the children of Pagans. After surviving many embarrassments during the war, it is now one of the most flourishing seminaries in the United States. Its funds consist chiefly of lands, amounting to about 80,000 acres of increasing value. Its revenue arising from the lands, in 1793, amounted annually to 140*l.* and by certain contracts then made, would amount in twelve years to 650*l.* The income from tuition is about 600*l.* per annum. The number of under-graduates, is, on an average, about 150*l.* The students are under the immediate government and instruction of a president, who is also professor of history; a professor of mathematics; a professor of languages; and two tutors. The college is furnished with a handsome library and a philosophical apparatus tolerably complete. A new college built of wood, 150 by 50 feet, and three stories high, was erected in 1786, containing 36 rooms for students. Three other public buildings belong to the college.

In 1801, an act passed for establishing an university in the town of Athens, in the state of Ohio, which now bears the name of the "Ohio University." The corporation is to consist of the governor of the state, for the time being, the president, and not more than 15 nor less than 10 trustees. The present endowment of this institution consists of two townships of land, amounting to 46,080 acres. Congress, in 1787, covenants with the Ohio company to give these lands in perpetuity for the purposes of an university.

Jefferson college, so named after the respectable and intelligent president, is a new foundation in the Mississippi territory.

Bowdoin college is situated in the district formerly called the province of Maine, in the village of Brunswick, upon the river called by the Indian natives Androscoggin, which name it still retains. The legislature, about the year 1794, incorporated certain persons for the purpose of establishing an university or college in the district of Maine, under the name of Bowdoin college, so called after the honourable James Bowdoin, esq. late governor of the Massachusetts. The legislature granted several townships of unsettled lands within the district of Maine to the college as a fund for its support,

ſupport, and the ſon of the gentleman above-named has been a very liberal benefactor to the inſtitution. Buildings have lately been erected for the accommodation of the ſtudents and preſident. The library, apparatus, and profeſſorſhips of the college are yet upon a limited ſcale; but its ſituation is favourable, and the activity of its patrons and friends, among whom we may mention, Benjamin Vaughan and Charles Vaughan, eſqs. cannot fail to promote its growing proſperity.

College, *Chelſea*. See Hospital and Chelsea.

College *of Civilians*, commonly called *Doctors Commons*; a college founded by Dr. Harvey, dean of the arches, for the profeſſors of the civil law reſiding in this city; where uſually, likewiſe, reſides the judge of the arches court of Canterbury, judge of the Admiralty, of the prerogative court, &c. with other civilians; who all uſed to live, as to diet and lodging, in a collegiate manner, commoning together: whence the appellation of *Doctors Commons*.

Their houſe being conſumed in the great fire, they all reſided at Exeter-houſe in the Strand, till 1672; when their former houſe was rebuilt, at their own expence, in a very ſplendid manner. To this college belong, beſides other officers, a number of proctors: who make themſelves parties for their clients, manage their cauſes, &c.: and ſeveral courts, maritime and eccleſiaſtical, as thoſe of arches, admiralty, prerogatives, delegates, and conſiſtory. The doctors are ſuch as having graduated at one of the univerſities, are afterwards admitted of the college of advocates belonging to theſe courts.

College, *Dulwich*. See Allen.

College, *Greſham*, or College *of Philoſophy*, a college founded by ſir Thomas Greſham, and endowed with the revenue of the Royal Exchange, and other premiſſes; one moiety of this endowment the founder bequeathed to the mayor and aldermen of London, and their ſucceſſors in truſt, that they ſhould find four able perſons to read, within the college, divinity, geometry, aſtronomy, and muſic, who are choſen by a committee of the common-council, conſiſting of the lord-mayor and three aldermen and eight commoners, and allowed each, beſides lodging, fifty pounds, per annum. The other moiety he left to the company of mercers, to find three other perſons, choſen by a committee of that company, conſiſting of the maſter and three wardens, during their office, and eight of the court of aſſiſtants, to read law, phyſic, and rhetoric, on the ſame terms; with this limitation, that the ſeveral lectures ſhould be read in term-time, every day in the week, except Sundays: in the morning in Latin, in the afternoon the ſame in Engliſh: but that in muſic to be read only in Engliſh. As the ſettlement of this college could not take place till after the death both of ſir Thomas Greſham and his lady, the two corporations could not proceed to act till the month of December, 1596, after the deceaſe of lady Greſham. Accordingly, in the choice of the firſt ſeven profeſſors, which was completed before the 31ſt of March in the following year, when they took their ſeveral apartments in the manſion-houſe, according to the allotment then made, the electors ſeem to have been deſirous of manifeſting an equal regard to both the univerſities; ſo that three were choſen from Oxford, and three from Cambridge, and the ſeventh, who was a graduate of both, upon the recommendation of queen Elizabeth.

By 8 Geo. III. cap. 32. the building appropriated to this college was taken down, and the exciſe-office erected in its room. Each of the profeſſors is allowed fifty pounds per annum, in lieu of the apartments, &c. relinquiſhed by them in the college, and is permitted to marry, notwithſtanding the reſtriction of ſir Thomas Greſham's will. The lectures are now read in a room over the Royal Exchange; and the city and mercers' company are required to provide a proper place for this purpoſe.

In this college formerly met the Royal Society, that noble academy, inſtituted by king Charles II. and celebrated throughout the world, for their improvements in natural knowledge. See their hiſtory and policy, under Royal Society.

College *of Heralds*, or College *of Arms*, a corporation founded by king Richard III., who, by charter bearing date the 2d of March, in the firſt year of his reign, made the kings, heralds, and purſuivants of arms, one body corporate by the name of "Le garter regis armorum Anglicorum, regis armorum partium auſtralium, regis armorum partium borealium, regis armorum walliæ, et heraldorum, proſecutorum, ſive purſevandorum armorum;" empowered them to have and uſe a common ſeal, and granted to them and their ſucceſſors, for the uſe of the twelve principal officers of the corporation, a houſe with its appurtenances, then called Colde Arbor, and ſituated within the pariſh of All-Hallows the Leſs, in the city of London; they finding a chaplain to celebrate maſs daily in the ſaid houſe, or elſewhere at their diſcretion, for the good ſtate of health of Anne his queen, and Edward, prince of Wales, during their lives, and for their ſouls after their deceaſe.

In conſequence of the Act of Reſumption, paſſed in the firſt year of the reign of king Henry VII., this houſe was ſeized into the king's hands, becauſe it was ſuppoſed to belong perſonally to John Writhe, garter, who then lived in it, and not to the officers of arms in their corporate capacity.

The officers of arms, during the reigns of Henry VII. and Henry VIII., frequently petitioned the throne for a grant of ſome houſe or place wherein to hold their aſſemblies, but without ſucceſs. King Edward VI., however, in a charter dated the 4th of June, in the third year of his reign, and by authority of parliament, endeavoured to make them ſome amends, by confirming to them all their ancient privileges, as to be free and diſcharged from all ſubſidies, in all realms where they make their demoure; as alſo from all tolls, taxes, cuſtoms, impoſitions, and demands, as well from watch and ward, as from the election to any office of mayor, ſheriff, bailiff, conſtable, ſcavenger, church-warden, or any other public office of what degree, nature, or condition ſoever.

Philip and Mary, by their charter bearing date the 18th day of July, in their firſt and ſecond years, re-incorporated the kings, heralds, and purſuivants of arms by their former names; and to the intent that they might reſide together, and conſult and agree amongſt themſelves for the good of their faculty, and for the depoſiting and ſecure preſervation of their records, inrolments, and other documents and papers, granted to them a meſſuage, with its appurtenances, called Derby Houſe, ſituate in the pariſh of St. Benedict and St. Peter, within the city of London, and in the ſtreet leading from the ſouth door of the cathedral church of St. Paul, to a place there called Paul's Wharf, and then late in the tenure of ſir Richard Sakevyle, knight, but theretofore parcel of the poſſeſſions of Edward, earl of Derby, and to be by the ſaid corporation held in free burgage of the city of London.

In the great fire of London, anno 1666, the college was entirely conſumed: but the heralds had the good fortune to ſave all their muniments and books, which were depoſited in the palace at Whitehall; from whence they were afterwards removed into the palace at Weſtminſter, near to the Court of Requeſts, whereupon public notice was given in the

the London Gazette, that the Heralds' Office was there kept. The college was afterwards rebuilt, and, as a regular quadrangular building, is considered one of the best designed and handsomest brick edifices in London, particularly the hollow archway of the great gate, which is esteemed a singular curiosity.

The corporation consists of three kings of arms, Garter, Clarenceux, and Norroy, six heralds, *viz.* Windsor, Chester, Lancaster, Somerset, York, and Richmond, and four pursuivants, *viz.* Portcullis, Rougedragon, Bluemantle, and Rouge-Croix; who all take precedency, according to the dates of their respective patents.

Arms of the college; argent, a cross gules between four doves rising azure.

Crest. On a ducal coronet or, a dove rising azure.

Supporters. Two lions rampant guardant argent, ducally gorged or.

COLLEGE *of Heralds* in Scotland, consists of Lyon king at arms, six heralds, and six pursuivants, and a number of messengers.

COLLEGE *of Justice.* See COURT *of* JUSTICE.

COLLEGE *of Merchants.* See BURSE.

COLLEGE, *Military, Royal,* was instituted in 1799, under the direction of twelve commissioners, a governor, and professor of mathematics. It consists of two departments, the senior, established at Wycombe, and the junior at Marlow, in Buckinghamshire, each under the care of a commandant, superintendant, and adjutant, and under the instruction of a number of professors, in different branches of science and literature.

COLLEGE *of Physicians,* a corporation of physicians in London; who, by several charters and acts of parliament of Henry VIII. and his successors, have certain privileges, whereby no man, though a graduate in physic of any university, may, without licence under the said college seal, practise physic in, or within seven miles of London, under the penalty of paying 5*l.* for every month they practised; with power to administer oaths, fine and imprison offenders in that and several other particulars: to search the apothecaries shops, &c. in and about London, to see if their drugs, &c. be wholesome, and their compositions according to the form prescribed by the said college in their dispensatory. By the said charter they, and their licentiates, are also freed from all troublesome offices: as to serve on juries, be constable, keep watch, provide and bear arms, &c. The project and plan of this institution were formed by Dr. Thomas Linacre, physician to Henry VIII., and patronized by cardinal Wolsey, at whose desire the king granted a charter, Sept. 23d, A. D. 1518, incorporating several persons of the medical class into a body, community, and perpetual college. To this college Henry granted various rights, powers, and immunities by his charter; such as a right to elect a president annually for the government of the college; to have a common seal; to purchase lands to a certain value; to sue and be sued by the name and title of "The president and community of the college of physicians in London;" and to make laws and regulations for the good government of the college, &c. &c. This charter was confirmed by parliament, A. D. 1523, 15 Hen. VIII. This institution was intended and calculated to raise the reputation of the medical profession, and prevent the people from being imposed upon by bold and ignorant adventurers, who sported with their lives, and robbed them of their money. These two acts of parliament, which were for some time strictly executed, had one remarkable effect: by greatly diminishing the number of practitioners, they made the regular practice of physic and surgery exceedingly lucrative. "The most effectual security against poverty," says Erasmus (Oper. t. v. p. 661.) "is the art of medicine, which of all arts is the most remote from mendicity."

The society had anciently a college in Knight-Rider-street, the gift of Dr. Linacre. Since that they have had a house built for them by the famous Dr. Harvey, in 1652, at the end of Amen-Corner, which he endowed with his whole inheritance in his life-time; but this being burnt in the great fire in 1666, a new one was erected at the expence of the fellows, in Warwick-lane; with a noble library, given partly by the marquis of Dorchester, and partly by sir Theodore Mayerne.

Of this college there are at present, a president, four censors, eight electors, a register, and a treasurer, chosen annually in October: the censors have by charter power to survey, govern, and arrest all physicians, or others practising physic, in, or within seven miles of London; and to fine, amerce, and imprison them at discretion.

The number of fellows was anciently thirty, till king Charles II., who renewed their charter in 1663, increased their number to forty; and king James II. giving them a new charter, allowed the number of fellows to be enlarged, so as not to exceed fourscore; reserving to himself and successors the power of placing and displacing any of them for the future. Since that time, they have been limited to no certain number, but remain candidates a year, before their admission as fellows.

The college is not very rigorous in asserting their privileges; there being a great number of physicians, some of very good abilities, who practise in London, &c. without their licence, and are connived at by the college: yet, by law, if any person, not expresly allowed to practise, take upon him the cure of any disease, and the patient die under his hand, it is deemed felony in the practiser.

According to the constitution of the college, or at least of certain by-laws which have been enacted, not, however, invariably adhered to, all physicians, but the graduates of Oxford and Cambridge, are excluded from the fellowship of the college. A late writer, in favour of the licentiates, after citing a variety of strong passages from the speeches of lord Mansfield and other judges, proceeds to remark; "It is asserted then upon the highest legal authority, that the college of physicians are unwarranted in making by-laws, which infringe the design and intention of the crown and parliament in their institution; and it has been proved that the by-laws, which exclude all graduates but those of Oxford and Cambridge from the fellowship of the college, without any investigation of their competency and fitness, are founded in usurpation;—an usurpation which cannot be justified by any possible construction of the charter, or acts confirming it. It is, therefore, demonstrated, that such by-laws are illegal, and that they may be annulled, and their pernicious consequences abolished." The practical conclusion, with respect to those whom the college will at present admit only to the rank of licentiates, is to claim admission to fellowships "under the charter of incorporation itself, on the broad basis of individual qualification, without the least regard to places of study, or to local graduation." The claim, however, has not yet been allowed. See Dr. Ferris's General View of the Establishment of Physic as a Science in England, &c." 8vo. 1795.

COLLEGE, *Royal, of Physicians,* in Scotland, is a corporation of physicians at Edinburgh, established by patent of Charles II. 29th November, 1681. This college consists of a president, two censors, a secretary, and the ordinary society of fellows. They have similar rights and privileges with those of the English college.

In Ireland there is likewise a college of Physicians, consisting of a president, vice-president and censor, treasurer, and a number of fellows.

College *of Singers*, at Rome. It is allowed unanimously by ecclesiastical writers, that it was the learned and active pope Gregory the Great, whose pontificate began in 590, who collected the musical fragments of such ancient hymns and psalms as the first fathers of the church had approved, and recommended to the primitive Christians; and that he selected, methodized, and arranged them in the order which was long continued at Rome, and soon adopted by the chief part of the western church.

The anonymous author of his life published by Canisius, speaks of this transaction in the following words: "This pontiff composed, arranged, and constituted the *antiphonarium*, and chants used in the morning and evening service." And Fleury, in his Hist. Ecclef. tom. viii. p. 150, gives a circumstantial account of the *scola cantorum*, instituted by St. Gregory. It subsisted three hundred years after the death of that pontiff, which happened in 604, as we are informed by John Diaconus, author of his life. The original *antiphonarium* of this pope was then subsisting; and the whip with which he used to threaten to scourge the boys; as well as the bed on which he reclined in the latter part of his life, when he visited the school in order to hear them practise. Two colleges were appropriated to these studies; one near the church of St. Peter, and one near that of St. John Lateran; both of which were endowed with lands.

It seems as if a college of singers for the education and exercise of the singers in the service of the papal chapel had always subsisted at Rome from the time of its establishment by Gregory.

It was from this college that the rest of Europe had masters to instruct the priests and choral singers in canto firmo. We learn from Venerable Bede, and from William of Malmsbury, that Austin the monk, commonly called the English apostle, who was sent from Rome by pope Gregory the Great, to convert the Saxons, instructed them in ecclesiastical music.

Bede tells us, that when Austin and the companions of his mission, had their first audience of king Ethelbert in the Isle of Thanet, they approached him in procession, singing litanies; and that, afterwards, when they entered the city of Canterbury, they sung a litany, and at the end of it, *Allelujah*.

Venerable Bede was himself an able musician; and he informs us, that in 680, John, Præcentor of St. Peter's in Rome, was sent over by pope Agatho to instruct the monks of Weremouth in the art of singing, and particularly to acquaint them with the manner of performing the festival services throughout the year, according to that which was practised at Rome. And such was the reputation of his skill, that "the masters of music from all the other monasteries of the north came to hear him; and prevailed on him to open schools for teaching music in other places of the kingdom of Northumberland."

And Charlemagne, finding the Roman chant superior to that of France, procured masters of pope Adrian, from the college of singers, established by Pope Gregory, to teach his subjects throughout his extensive dominions. And Theodore and Benedict, two chanters of great learning and abilities, who had been instructed by St. Gregory himself, were elected for that purpose. Adrian likewise granted to him *antiphonaria*, or choral books of that saint, which he had written himself in Roman notes.

Adrian; Stephen, monk of Canterbury; friar James, and many others, are celebrated by Bede for their skill in singing after the Roman manner. It was then the custom for the clergy to travel to Rome for improvement in music, as well as to import masters of that art from the Roman college. At length the successors of St. Gregory, and of Austin his missionary, having established a school for ecclesiastical music at Canterbury, the rest of the island was furnished with masters from that seminary.

It would be easy to prove, that good taste in canto firmo, as well as in dramatic music, has at all times been derived from the Italian school. Much has been said by travellers, and writers on music, of the refined and polished manner of performing the famous *miserere* of Allegri, in the pontifical chapel; and it will be easy to judge of the abilities of the singers educated in the Roman college, to do justice to every composition in that service, from the account given by Angellini Bontempi, in his "History of Music," of their education and course of study. "The disciples of the Roman school," says this author, "were obliged to exercise themselves in difficult intonations an hour every day, in order to acquire a facility of execution; another was spent in the practice of shakes; another in rapid passages; another in the study of literature, and another in taste and expression, in the presence of the master, who obliged them to sing before a mirror, in order to avoid every grimace or improper motion of the muscles, either by furrowing the forehead, knitting the brows, or distorting the mouth: and all these studies were but the employments of the morning. In the afternoon, half an hour was spent in harmonics, or the theory of sound; another in counterpoint, upon a plain song; an hour in receiving rules of composition from the master, and putting them in practice on paper; another in the study of languages; and the rest of the day in practising on the harpsichord, in composing a motet or anthem, a song, or in some other kind of writing, suitable to the genius and progress of the scholar: and these were the common exercises on those days, when the students were not allowed to quit the college; but when they were permitted to go out, they frequently went to sing at the echo, without the Porta-Angelica, near mount Marius, where, by listening to the answers, or reflection of the passages, they could judge of their own defects; at other times they were either employed in singing at the musical performances in the churches of Rome on days of festivals, or, at least were allowed to go thither to hear the great professors who flourished in the pontificate of Urban VIII., who reigned from the year 1624 to 1644. At their return to college, they employed the rest of their time in practising after these models, and in giving reasons to the master for what they did; who, in his turn, used to read lectures upon the most refined and useful mysteries of the musical art." Historia Musica, Perugia, 1695

College, *Sion*, or the college of the London clergy; which has been a religious house time out of mind, sometimes under the denomination of a priory, sometimes under that of a spital, or hospital; at its dissolution under 31 Hen. VIII. it was called Elsyn's *Spital*, from the name of its founder, a mercer, in 1329.

At present it is a composition of both, *viz.* a college for the clergy of London, who were incorporated in 1630, in pursuance of the will of Dr. White, under the name of the *President and Fellows of* Sion-College; and an hospital for ten poor men, and as many women.

The officers of the corporation are the president, two deans, and four assistants; who are annually chosen from among the rectors and vicars of London; and are subject to the visitation of the bishop. The fellows of this college are all the incumbents of parishes within the city and its liberties. They have a good library, built and stocked by Mr. Simpson, and furnished by several other benefactors, chiefly for the clergy

clergy of the city, without excluding other ſtudents on certain terms; and a hall, with chambers for ſtudents, generally occupied by the miniſters of the neighbouring pariſhes.

College *of Surgeons, Royal*, was incorporated by charter in 1800, under a maſter, two governors, and 18 aſſiſtants. Its houſe is in Lincoln's Inn Fields. There is alſo at Edinburgh a royal college of ſurgeons of late inſtitution, under a preſident, treaſurer, and honorary fellows. This college is authoriſed for carrying into execution a ſcheme for providing for their wives and children, &c.; and for examining and licenſing, if found qualified, all practitioners in ſurgery, within certain limits.

College *de Propaganda Fide*, was founded at Rome in 1622, by Gregory XV. and enriched with ample revenues. It conſiſts of thirteen cardinals, two prieſts, one monk, and a ſecretary; and was deſigned for the propagation and maintenance of the Roman religion in all parts of the world. The funds of this college have been very conſiderably augmented by Urban VIII. and many private donations. Miſſionaries are ſupplied by this inſtitution, together with a variety of books ſuited to their ſeveral appointments. Seminaries for their inſtruction are ſupported by it, and a number of charitable eſtabliſhments connected with it, and conducive to the main object of its inſtitution.

Another college of the ſame denomination was eſtabliſhed by Urban VIII. in 1627, in conſequence of the liberality of John Baptiſt Viles, a Spaniſh nobleman. This is ſet apart for the inſtruction of thoſe who are deſigned for the foreign miſſions. It was at firſt committed to the care of three canons of the patriarchal churches; but ever ſince the year 1641, it is under the ſame government with the former inſtitution.

College, *Veterinary*, a recent inſtitution formed at St. Pancras, in the vicinity of London, for the reformation and improvement of farriery, under the direction of a preſident, 10 vice-preſidents, a profeſſor, and treaſurer. This inſtitution cannot otherwiſe than be regarded by every reflecting perſon, as an object of national importance as well as of private utility; and in both theſe views merits liberal encouragement.

Collegial. See Collegiate.

COLLEGIANS, Collegiani, Collegiants, in *Eccleſiaſtical Hiſtory*, a religious ſect formed among the Arminians and Anabaptiſts in Holland, about the beginning of the ſeventeenth century; ſo called, becauſe of their colleges or meetings, twice every week, where every one, females excepted, has the ſame liberty of expounding the Scripture, praying, &c.

They are ſaid to be all either Arians, or Socinians; they never communicate in the college, but meet twice a year from all parts of Holland at Rhinſbergh, whence they are alſo called *Rhinſberghers*, a village two miles from Leyden, where they communicate together; admitting every one that preſents himſelf, profeſſing his faith in the divinity of the holy Scriptures, and reſolution to live ſuitably to their precepts and doctrines, without regard to his ſect or opinion. They have no particular miniſters, but each officiates as he is diſpoſed. They never baptize without dipping.

At Rhinſberg they have ample and convenient houſes for the education of orphans, and the reception of ſtrangers; and here they remain together during the ſpace of four days, which are employed in hearing diſcourſes that tend to edification, and exhortations that are principally deſigned to inculcate brotherly love, and ſanctity of manners. Thoſe of the brethren that reſide in the province of Frieſland, have an annual meeting at Lewarden, where they adminiſter the ſacraments, as the conſiderable diſtance at which they live from Rhinſberg renders it inconvenient for them to repair thither twice a-year. Their community comprehends perſons of all ranks, orders, and ſects, who profeſs themſelves Chriſtians; though their ſentiments concerning the perſon and doctrine of the divine founder of Chriſtianity be extremely different. It is kept together, and its union maintained, not by the authority of rulers and doctors, the force of eccleſiaſtical laws, the reſtraining power of creeds and confeſſions, or the influence of certain poſitive rites and inſtitutions, but merely by a zeal for the advancement of practical religion, and a deſire of drawing inſtruction from the ſtudy of the holy ſcriptures. In ſuch a community, in which opinion is free, and every one is permitted to judge for himſelf in religious matters, diſſenſions and controverſies can ſcarcely be ſuppoſed to occur. However diſſenſions took place, the conſequence of which was a diviſion of the collegiants into two parties, which held their aſſemblies ſeparately, at Rhinſberg. This diviſion happened in the year 1686; but it was healed about the commencement of the following century, by the death of thoſe who had principally occaſioned it; and then the collegiants returned to their former union and concord. Moſh. E. H. vol. v.

COLLEGIATE, or Collegial *churches*, are thoſe which have no biſhop's ſee, yet have the ancient retinue of the biſhops, the canons, and prebends. Such are, among us, Weſtminſter, Rippon, Windſor, &c. governed by deans and chapters.

Of theſe collegiate churches, there are two kinds; ſome of royal foundation, others of eccleſiaſtical foundation; each of them, in matters of divine ſervice, regulated in the ſame manner as the cathedrals.

There are even ſome collegiate churches which have the epiſcopal rights. Some of theſe churches were anciently abbeys; which, in time, were ſecularized. The church of St. Peter's, Weſtminſter, was anciently a cathedral; but the revenues of the monaſtery being, by act of parliament, 1 Eliz. veſted in the dean and chapter, it commenced a collegiate church.—In ſeveral cauſes, the ſtyling it cathedral, inſtead of collegiate church of Weſtminſter, has occaſioned error in the pleadings.

COLLEONE, Bartholomew, in *Biography*, was born in the year 1400, of a family of diſtinction at Bergamo, in Italy. He was famous among the ſoldiers of fortune, having been trained from his youth in the military art. He firſt ſerved under Bracchio de Montone, and then entered into the ſervice of the queen of Naples, who was indebted to him for the recovery of her dominions. He rendered important ſervices to the Venetians, by whom he was handſomely rewarded; but owing to a quarrel with a noble Venetian, he went over to the duke of Milan, and ſerved with great reputation, firſt under Viſconti, and then under Francis Sforza. He again enliſted in the Venetian ſervice; and was in 1458, made their generaliſſimo; an office which he held twenty years with the higheſt reputation to himſelf, and to the terror of the enemies of the republic. Colleone was a patron of literature, and was fond of the company of learned men, to whoſe diſcuſſions on philoſophical ſubjects he always paid the moſt marked attention. He founded monaſteries, built churches, and inſtituted various charities. But notwithſtanding theſe inſtances of his liberality, he amaſſed great wealth, which he bequeathed to public purpoſes. He died in 1475,

at

at his castle of Malpaga; and the senate of Venice erected an equestrian statue to his memory. In his youth, Colleone was distinguished as well for his courage, as for bodily strength and agility; and it is asserted that when completely armed, he could run faster than the lightest footman, and without arms he could surpass a horseman on full gallop. This vigour he preserved to almost the last. In the latter part of his life he was held in so much estimation, that no prince or person of rank, however exalted, who travelled in the part of the country in which he lived, ever neglected to pay him a visit. On his dying bed, he gave it, as advice to the Venetians, that they should never give so much power to a general as he had possessed. After his death 4000 soldiers refused to obey any other chief, and served 15 years without a leader, diligently practising the discipline he had taught them. Moreri.

COLLEONI, Girolamo, a painter of Bergamo, whose style so much resembled that of Titian, that his picture of the marriage of St. Caterina in the gallery of the Carrara family, was for a long time considered the work of that great master; till at length the inscription Hieronymus Colleo, 1555, was discovered, and the credit of the performance restored to its right owner. It is said of this master, that having found inferior artists and strangers preferred to the honour of executing public works, whilst he himself was passed by unnoticed, he formed the resolution to quit his ungrateful country, and sought an asylum at the court of Madrid. Before, however, he departed, he painted the figure of a horse, of the merit of which no idea can now be formed, except from the prodigious encomiums bestowed upon it by various writers: under the picture was this proverb: *nemo propheta in patria*. Besides the picture above-mentioned in the Carrara gallery, there are still some remains of his fresco in Bergamo. He flourished as early as 1532. Lanzi. Storia Pitt.

COLLET, John, an English painter, whose pictures of ludicrous subjects, in the manner of Hogarth, are well known. Heinecken mentions several prints from his works, and two were etched by himself; one of which represents antiquarians smelling at the chamber-pot of queen Boadicea; and the other, a monkey, who is pointing to a very dark picture of Moses striking the rock, probably in ridicule of the connoisseurs of that period, who thought every piece deserving of notice, in proportion as it was black and unintelligible. Strutt says, that Collet flourished in 1760, and Heinecken informs us, that he died in 1780.

Collet, Philibert, was the son of a notary, and was born at Chatillon les Dombes, in 1643. He pursued his studies at Lyons, in the college of the Jesuits, of which order he became a noviciate, but quitted their society at the age of 22, and dedicated himself to the profession of the law. By the liberality of sentiment which he displayed in his writings, he excited an ill-founded suspicion, that he was an enemy to religion. This imputation has, indeed, been in all ages the lot of those who have impugned ecclesiastical abuses, and could not fail to be levelled at Philibert, who attacked the power of the priests, in a "Treatise on Excommunications;" a "Tract on Usury;" "Discourses on Tythes and Alms," and on the "Cloystering of Nuns." He died in 1718, after a solemn declaration, that he did not repent of any of these publications which had excited against him no ordinary degree of prejudice.

Collet, Richard, a performer on the violin with a full tone and strong hand. He was leader of the band at Vauxhall, from its first opening to the death of Jonathan Tyers, where he executed the compositions of Corelli, Handel, Geminiani, very accurately, but without taste or expression; so that he always remained an inelegant player.

Collet, Thomas, a second rate violoncello player, in a much lower form than his brother. He was lame upon one of his legs; and upon his instrument his hand could hardly be said to be otherwise.

Collet, Peter, a priest and doctor of theology, was born in the year 1693, at Ternay, a town in the province of Vendome, in France. His works, which treat chiefly on subjects of controversial divinity, are very voluminous, but not very valuable. The principal of them are "Theologia Moralis Universa," in 17 vols. 8vo.; "Institutiones Theologicæ," in 7 vols. 12mo.; and the "Life of St. Vincent de Paul," in 2 vols. 4to. He died in 1770, having sustained, through a long and active life, the character of a pious and learned divine.

Collet, in the *Glass Trade*, that part of a glass vessel which, in the manufacture, sticks to the hollow iron by which the metal is first taken out of the melting pot. This is broken off before the vessel is fashioned, and is never seen in the least mark, when finished.

These they throw together, and afterwards grind down, and put into the green glass metal, for the purest green glass, but never into any other, though they be the product of the finest virgin metal.

Collet, among *Jewellers*, the small horizontal plane, or face, at the bottom of the brilliant.

Collet *de Canon*, the smallest or most diminished part of the cannon, lying between the astragal and muzzle.

Collet-de dezes, *le*, in *Geography*, a town of France, in the department of the Lozere, and district of Mende, 12 miles S. of Villefort.

COLLETIA, in *Botany*, (so named from Collet, a French botanist.) Lam. Ill. 359. Willd. 411. Juss. 380. Vent. 3. 472. Class and order, *pentandria monogynia*. Nat. Ord. *Rhamni*, Juss. *Rhamnoideæ*, Vent.

Gen. Ch. *Cal.* one-leafed, pitcher-shaped, permanent at the base, furnished on the inside with five squamiform plaits, called petals by Ventenat; border five-cleft; segments egg-shaped, reflexed. *Cor.* none. *Stam.* Filaments five, awl-shaped, very short, inserted at the top of the calyx between the segments of the border; anthers egg-shaped. *Pist.* Germ superior, trigonous; style cylindrical; stigma three-lobed. *Peric.* Capsule tricoccous, seated on the permanent base of the calyx; cocci somewhat kidney-shaped, cohering at the inner side. *Seeds* solitary.

Eff. Ch. Calyx pitcher-shaped, five-cleft, with five squamiform plaits on the inside. Corolla none. Capsule tricoccous, with three seeds.

Sp. 1. C. *spinosa*. Lam. Illust. tab. 129. Joseph Jussieu. Commerson. "Leaves oblong-elliptical, entire or slightly toothed at the tip." A very spinous, much-branched shrub. *Branches* nearly opposite, without leaves on the upper part, and furnished with long lateral and terminal spines. *Leaves* near the bottom of the branches, small, on short petioles. *Flowers* lateral, nodding; peduncles short, one-flowered, solitary, or two together, generally at the base of the spines. A native of Peru and Brazil. 2. C. *serratifolia*. Vent. Choix des plantes. "Leaves oblong, obtuse, acutely serrated; flowers without petals, *i. e.* without the squamiform plaits." A shrub, with the habit of a lycium. 3. C. *ephedra*. Vent. Choix des plantes. "Leafless; branches erect, implicated, ending in a spine; flowers glomerated at the knots of the branchlets." The two last species are natives of Peru, discovered by Dombey. Not having present access to Ventenat's splendid work, we have taken the specific characters from the Annals of Botany.

COLLETICS,

COLLETICS, Colletica, from κολλητικος, something that has the virtue of gluing together, of κολλα, *gluten*, in *Medicine*, such remedies as join and glue together the separated parts, or lips, of a wound or ulcer; and thus re-establish them in their natural union.

Among colletics are ranked litharge, aloes, myrrh, &c. See Agglutinant.

COLLI, Le, in *Geography*, a town of Naples, in the province of Abruzzo Ultra; 15 miles west of Celano.

Colli *interspinales*, in *Anatomy*. See Interspinales.—*Intertransversales*. See Intertransversales.—*Transversalis*. See Transversalis.

COLLICLÆ, is used by some, as Steno, for the carunculæ *lacrymales*.

COLLIER, Jeremy, in *Biography*, an English nonjuring bishop, was born at Stow Qui, or Quire in Cambridgeshire, Sept. 23, 1650. He was educated by his father, a clergyman, and some time master of the free-school at Ipswich, and in 1669 he was admitted a poor scholar of Caius college, under the tuition of Mr. John Ellys. Here he took his degrees, and was afterwards successively ordained deacon and priest, by the bishops of Ely and London. For some time he officiated as chaplain to the countess dowager of Dorset at Knowle; he was afterwards presented with the living of Ampton, in Suffolk, where he resided till 1685, when he resigned on being appointed lecturer at Gray's Inn. After the revolution he refused to take the oaths, and became a zealous partizan of the abdicated sovereign. On account of a pamphlet entitled "The Desertion discussed," which he published in 1688 in opposition to one by Dr. Burnet; he was imprisoned in Newgate, from whence he was discharged without trial, and between this period and the year 1692, he published several other pamphlets which rendered him an object of extreme jealousy to the crown. He became still more obnoxious to government by a journey at this time into Kent, which led to a suspicion that he held a correspondence with the exiled James; he was accordingly arrested, examined before the earl of Nottingham, and committed to the Gate-house. He was again released for want of evidence of any criminal designs, and was admitted to bail. So strict, however, were Mr. Collier's principles, that he shortly after condemned his own want of consistency in giving bail; upon which he surrendered himself before lord chief justice Holt, in order that he might free his sureties, and was committed to the King's Bench, but upon the application of his friends, that excellent and upright judge discharged him in a few days. He then published a justification of himself, in a work entitled "The Case of giving Bail to a Pretended Authority examined." This was followed by several other tracts, which, though hostile to the new order of affairs, do not appear to have excited the attention of government. But, in 1696, he openly, in conjunction with two other nonjuring clergymen, absolved, at the place of execution, sir John Friend, and sir William Perkins, who had been convicted of engaging in the assassination plot. For this he was prosecuted to outlawry, in which state of legal incapacity he remained unmolested through the remainder of his life. Between the years 1697 and 1707, Mr. Collier published three volumes of essays on moral subjects, which obtained a very favourable reception by his contemporaries, but they are now fallen into disrepute. In 1698, he obtained a large share of celebrity for his piece entitled "A short View of the Immorality and Prophaneness of the English Stage, together with the Sense of Antiquity on this Argument." Mr. Collier in this work attacked most of the dramatic writers of the day, with so much force and ability, that those who ventured to engage with him in the controversy, were, in the public opinion, completely defeated. Without noticing the other tracts which he wrote on this subject, we pass on to his translation of Moreri's Great Historical Dictionary, which consisted of four volumes folio, published at different times, with the addition of a great number of new articles. During the reign of queen Anne, several ineffectual attempts were made to reconcile Mr. Collier to the existing government. Preferment in the church was offered to him, which he rejected, and he maintained his principles to the last. In 1702, he published the first volume "Of an Ecclesiastical History of Great Britain," which he followed by a second in 1714. This work, on which he bestowed great pains, was not remarkable for the impartiality, which it behoves the faithful historian to maintain in all subjects of dispute. His attacks on the principles and conduct of some of the most active promoters of the reformation, and of others who held opposite opinions to those which he had himself embraced, exposed him to the censures of literary characters of the first respectability, particularly of the bishops Nicholson, Burnet, and Kennet. Previously to the appearance of the second volume of his history, Mr. Collier had been privately consecrated a bishop by Dr. Hickes. In 1725 he published "Discourses upon Practical Subjects," which was his last work of any moment, and on the 26th of April, in the following year, he died of the stone, a disease to which he had been subject many of the last years of his life.

Bishop Collier was a man of intrepid courage, indefatigable industry, and of the most unsullied integrity. It is much to be regretted that a person of such talents, and possessed of so great a degree of ardour, had not embarked in a better cause, and thus have been distinguished on the side of civil and religious liberty, on which the best interests of man depend. Biog. Brit.

Collier, in *Geography* a town of America, in North Carolina; 11 miles N.E. of Wilmington.

COLLIERS, are vessels employed to carry coals from one port to another; and serving as an excellent nursery for seamen.

COLLIERY. Under the article Coal we have recently given the history of its mines and trade in Britain, its laws, the classification and description of different sorts of coal, the practice of coal-mining, and some of the principles to be observed in searching for coals; this last part admitting of farther and more general elucidation, we shall resume the subject in this place, and treat of the different opinions which naturalists have held, respecting the origin and formation of coals.

Mr. Richard Kirwan, a most indefatigable collector of facts relating to geology, when speaking of carboniferous soils or coal measures (Geological Essay, p. 290, &c.), states these to be either chiefly argillaceous or arenilitic, or both together, or of the trap kind, or calcareous; the circumstances of these, and of the coal found among them most worthy of notice, he states to be the following; *viz.*

1°. They commonly form distinct strata, or beds, one over the other to a great depth. The strata of coal are usually called *seams* (beds); it is very seldom found in irregular heaps (pipe-veins, bellies, nests), or veins (loads, fissures, rake veins, &c.).

2°. These seams are scarcely ever found *single*, but those whose thickness does not exceed 14 or 15 inches, are rarely worked.

worked. At Whitehaven five were lately worked, at Newcastle three, at Liege 20. The highest seams, and next the surface, are generally the worst (see §. 7°), but the deepest are not always the best.

3°. The thickness of different beds of coal is variable, from half an inch or less to 5 or 6 feet; but not unfrequently it amounts to 25 or 30 feet, and in some rare instances to 80 feet or more. No such seam as this last has occurred in Great Britain.

4°. Seams of coal generally occupy a considerable extent both in length and breadth, and whatever the thickness of each may be, it is commonly constant for a considerable space, as a mile or two miles; instances of a contrary kind seldom occur, unless the seam be disturbed by some obstruction (see § 16°), or at the extremities of a coal-soil, (coal-measures), or in an extent exceeding two miles.

5°. In the same stratum (seam) if exceeding 3 or 4 feet in thickness, the coal is seldom exactly of the same quality.

6°. Different seams of coal are separated from each other, by at least one, but generally by several strata of earth or stone (See article COAL); these, in a considerable extent, preserve also an uniform thickness.

7°. The uppermost seam of coal is commonly soft and dusty; it is vulgarly called *smut*.

8°. Seams of coal, and also their concomitant strata, are generally parallel to each other, unless an uncommonly thick stratum of earth, 150 or 200 feet thick, intervenes. Their number and order are also similar, to a considerable extent, yet variable in the same district and soil.

9°. In many of the concomitant strata, particularly of shale, bituminous shale, indurated clay, and sand-stone, particles of coal are found interspersed.

10°. The strata that immediately cover coal, and thence called its *roof* (crop), are shale, bituminous shale, or sand-stone; rarely any other. But they are also often found at a great distance above it.

11°. The strata on which coal reposes, and thence called its *floor*, *sole*, or *pavement*, are also sand-stone, shale, indurated clay, or semi-protolite (a reddish sand-stone or breccia). This last would, says Mr. Kirwan, in most cases, be found in its floor, if the mines were sunk deep enough to reach it. Granite has also been found in its floor in a few instances. In trap soils, trap or basalt is said to form sometimes the roof, and sometimes the sole of a seam of coal, but, in strictness, it is believed, shale mostly intervenes.

12°. Impressions of plants, particularly of the cryptogamic and culmiferous kind, are most frequently found in shale and bituminous shales that accompany coal, or which are found in coal mines, sometimes on sand stone, but very rarely on the coal itself. Roots also frequently appear in the indurated clay. Trees carbonated, or bituminated, sometimes repose on coal, or are found under it. Fluviatile (or river) shells, muscles, and land-snails, often occur; sea-shells seldom.

13°. Argillaceous iron ore is sometimes met with among the carboniferous strata of an argillaceous soil; and martial pyrites, either found, or much oftener oxygenated, and mixed with the substance of the coal.

14°. The *stretch* or *course* (drift, run) of seams of coal, and of their attendant strata, is commonly between E. and W. or N.E. and S.W. There are, however, a few exceptions to this rule.

: The *dip* (or pitch) of coal is exceedingly variable, sometimes nearly horizontal, sometimes from 25° to 45°, sometimes 75°, rarely approaching still more to the perpendicular.

16°. The uniform course (or plane) of seams of coal, and of the strata that accompany them, is frequently interrupted by obstructions, called *slips*, *dykes*, *troubles*, *faults*, (hitches, traps, breaks, fissures, loads, knots). These never fail to elevate (rise, upcast, uptrap) or depress (sink, downcast, downtrap) the strata beyond them; or rather, the strata on each side of them are found at different heights. This observation is general, being found to hold good in every part of Britain, as well as on the continent. The inequality of the height amounts from a few inches to 120 feet, but so great an inequality is rare, and has been found only in Derbyshire. In Germany it seldom exceeds, and scarcely amounts to, 50 feet.

17°. It has been observed in Britain, that if the *slip*, &c. overhangs (hades) on one side, and consequently forms an acute angle with the seam of coal which it cuts, the continuation of the stratum will be found *lower* on the other side of the slip, and consequently, *vice versâ*, if it recedes from (underlays), or forms an obtuse angle with the seam of coal on the one side; the continuation of the seam will be found higher on the other side, as in *Plate* I. *fig.* 1. of *Geology*, where *a* and *b* denote the interrupted seam of coal, and *c c*, the obstruction or *slip*, &c.

18°. These *slips*, &c. (or the matter filling them) sometimes consist of indurated clay, sometimes of sand-stone, both different from such as form the strata, but more frequently of some species of stone that never compose the strata of coal-mines, except, perhaps, rocks of the trap species; their thickness amounts in various mines, from a few inches to several yards. Nodules of coal are sometimes found in the slips, and water is frequently lodged in them. They often descend from the surface to the greatest known depths.

19°. The disposition of the strata below the surface seldom conforms to the figure of the surface. The former is often regular, when the latter is broken and uneven, and *vice versâ*; very frequently the strata dip into a hill, against the rise of the surface, or cross it in a right or diagonal line.

20°. The deepest mines known are those of Namur, some of which are said to descend 2400 feet, or 400 fathoms.

21°. The seams of coal, where in contact with their *roof*, *floor*, or *slip*, have a smooth, polished, glistening surface, which shews they were originally soft.

To the above we have, in parenthesis, added several synonyms for rendering them more intelligible in different districts; we subjoin other general conclusions of this ingenious author, relative to coals, with occasional synonyms of our own, and number them in a series following the above, for the convenience of reference: *viz.*

22°. That the quantity of earthy or stony matter in the most bituminous coal, bears no proportion to the weight of that coal; bituminous coal is capable of being charred (see COKE); and then it is a substance almost entirely resembling vegetable charcoal, which, on combustion, scarcely leaves $\frac{1}{70}$th of its weight of argil or stony matter. Geol. Ess. p. 316.

23°. That mines of *wood-coal* (brown-coal, Bovey-coal, surturbrand) have no uniformity in the thickness of their seams of wood-coal (as in § 4°); on the contrary, in the most considerable of these, an uniform decrease of thickness from the place in which the wood was first heaped, is observed. Ibid 321.

24°. That seams of real mineral coal, and those of earth or stone that accompany them, are observed to preserve their parallelism (noticed § 8°) even after an interruption by a slip or dyke, whether elevated or depressed. But in mines of wood-coal, no such parallelism, nor even any distinct number of strata prevail, but the whole appears to be one stratum, irregularly divided by masses of clay or stone. Ibid.

25°. That mines of wood-coal present sudden elevations or depressions in the same stratum; mines of real mineral coal never. Ibid 322.

26°. That

26°. That there are no flips or dykes in wood coal mines; thofe of genuine coal abound in them. Ibid.

27°. That wood-coal is frequently covered with round fragments of quartz; genuine coal never. Ibid.

28°. That there is in the mufeum of Florence, a cellular fand-ftone, the cells of which are filled with genuine mineral coal. Could this have been wood?" Ibid.

29°. That genuine coal is feldom found in plains, but wood-coal frequently is, according to Voight Pract. Ibid. 323.

30°. That the impreffions obferved on real coal, are thofe of herbaceous plants, as fern, &c.; the impreffions of refiniferous plants have never been difcovered on the ftrata that accompany coal, and the trees found are commonly birch or oak. Ibid. 318.

31°. That the traces of land vegetables, and not of marine vegetables, are found on the ftrata that cover feams of coal, or on thofe on which thefe feams reft, or on both. Sea-fhells are fcarcely ever found among them, and much lefs the bones of fifh: that, on the contrary, reeds or rufhes, and fluviatile fhells, have been found in the ftrata that cover coal. Ibid. 323.

32°. That common falt is never found in coal-mines, except when in the neighbourhood of falt fprings; but on the contrary, alum and vitriol. Ibid. 324.

33°. That carbonaceous ftrata never prefent a conic elevation on both fides of a difruptured ftratum, as would be the natural refult of an impreffion from below. Ibid. 337.

34°. That coal is never to be expected in primeval mountains, as granite, gneifs, &c., but that on the fides of thefe, particularly if very high, or in the hanging level that flopes from them to fome river or valley, it may be fought. Ibid. 347.

35°. That there is ftill a greater probability of finding it in the neighbourhood of mountains of argillaceous porphyry. Ibid.

36°. That it may be fought with probability of fuccefs in fand-ftone mountains, if fand-ftone and clay alternate, or fand-ftone, clay, and argillaceous iron ore. Ibid. 348.

37°. That in any elevated land in which fand-ftone and fhale with vegetable impreffions, or indurated clay and fhale, or bituminous fhale, form diftinct ftrata, or clay, iron ore, and fhale, with or without ftrata of fand, coal may well be expected. Ibid.

38°. That if fand-ftone be found under lime-ftone, or if they alternate with each other, and, particularly, if indurated clay and fhale form any of the ftrata, they afford a probable indication of coal; otherwife coal is very rarely found in, or under lime-ftone. Ibid.

39°. That coal is very feldom found with argillite, and fuch as has been is of the uninflammable kind. Ibid.

40°. That where trap, or whin and clay alternate, and more efpecially trap and fand-ftone, coal may be expected; it is often, but not regularly, found under bafalt; wood-coal is fometimes found under both. Ibid.

41°. That coal frequently burfts out on the furface, or on the fides of hills, in a withered ftate, which diffufes itfelf to a diftance from its origin, and requires an experienced miner to trace it truly to the feam to which it belongs. Ibid.

Such are the valuable obfervations of Mr. Kirwan, on the probable exiftence of coal in certain fituations, and on its pofition and relation to the adjoining ftrata, &c. Thefe obfervations are for the moft part unexceptionably true, and will be found confiftent with what we have delivered on this fubject, under the article COAL; but a few of them feem to require fome remarks in this place.

§ 3°. Under the names of different collieries we fhall take occafion to mention fuch feams of coal as are remarkable for their thicknefs, or other properties. The limitation of two miles, as the extent of regularity in coal feams, mentioned in § 4°, feems inconfiftent with the multiplied obfervations of Mr. Smith and other recent obfervers; fometimes two or more veins of coal which are feparated only by thin beds of fhale, or other bituminous matter unfit for ufe, are found to unite, owing probably to the diffufion of the earthy matter more generally among the coal, inftead of its forming diftinct layers therein; but generally, in purfuing the feam further, the coals feparate again; the extremities of a coal foil, can, in our opinion, only be found in the regular ending or out-crop of the meafures, (fee *Ending of* STRATA); or, where the ftrata on one fide of an obftruction or fiffure have been carried away by an abrafion or denudation of the elevated ftrata, of which we fhall give fome account, and mention feveral curious inftances in England, under the term DENUDATION. We are not inclined to think, that thick intervening meafures are more likely to alter the parallelifm of feams of coal, as mentioned § 8°, than thin ones; the contrary opinion has probably in fome cafes arifen from comparing the feam on different fides of a fault or fiffure, which hades or declines confiderably from a vertical pofition. Under the article COAL, we have explained how different borings or finkings in the fame diftrict, may differ materially, or perhaps entirely, owing to one being begun higher up on the meafures or feries of ftrata than the other, otherwife, we believe, that *the fame* ftratum will be found to have the fame fucceffion of ftrata under it. And here it may be neceffary to note, that a place being *higher up* on the feries of ftrata, has no relation to its actual elevation compared with the centre of the earth, or with a level line, as truly obferved by Mr. Whitehurft, (Enquiry p. 153,) but the loweft known ftrata in many diftricts are feen on the greateft heights; this we fhall amply illuftrate by examples, in the progrefs of our work. See *Order of the* STRATA.

The femiprotolite, mentioned § 11°, certainly has no exiftence in a large portion of the Britifh coal-mines, if it exifts in any of them; the theory adopted by our author, of granite forming the foundation in every inftance, and generally with a breccia or femiprotolite upon it, is difproved in innumerable inftances by Mr. Smith's maps and fections, fhewing the actual fucceffion of ftrata throughout the country.

We are of opinion with M. Blumenbach (Hanbuch der Natur. Gefch 703), that moft, if not all, of the vegetable foffil remains are *incognita*, and cannot be identified with any recent or known plants of the prefent race (§ 12° and 30°). The recent determinations of M. Cuvier declaring moft of the offeous remains from the ftrata, hitherto difcovered, to be *incognita*, will probably, we think, when the proper diftinction is made between the regular ftrata foffils, and thofe which ought, according to our remark under the article COAL, to be confidered as *gravel*, as *recent*, or as *peat* foffils, be much further extended, perhaps fo far as to include every animal remain which is found actually lodged in the ftrata; the diftinction, therefore, between *river* fhells and *land* fnails as accompaniments of coal, nearly to the exclufion of *fea* fhells or marine remains, we confider a mere hypothefis, as we fhall take future opportunities of fhewing.

It is not univerfally true, as mentioned § 16°, that *flips*, *dykes*, &c. never fail to elevate or deprefs the ftrata, or to occafion an inequality in their levels; (fee our defcription of dykes in the article COAL); the inftances being numerous both in the coal meafures and other ftrata, where a fiffure of confiderable width makes no fenfible alteration in the continuity of the planes of the ruptured ftrata. The alterations of level which fiffures occafion, are alfo much greater in numerous

ous

ous inſtances, than our author admits; beſides thoſe mentioned, (COAL), we might ſtate on the authority of Mr. Martin, that down-caſts of 40 to 100 fathoms are not uncommon in the ſtrata of what he denominates the Mineral Baſon of South Wales. (Phil. Trans. 1806. p. 342). That the diſlocations of the ſtrata (§ 17°) have been gentle and gradual, (Geol. Eſſays, 333), we cannot ſuppoſe, much leſs that the extraneous matters which fill the fiſſures (§ 18°) were of prior origin to the ſtrata themſelves, and occaſioned the overhanging or hading of the fiſſures, as our author has ſuppoſed, page 334. We have reaſon to hope, that theſe and ſeveral other hitherto unexplained phenomena of the ſtrata, will be fully made out by the new lights which we ſhall be enabled to throw on the ſubject, ariſing out of the diſcoveries of Mr. Smith, above alluded to.

That ſome rare inſtances have occurred of the ſtrata underneath, dipping in a contrary direction to thoſe near the ſurface, § 19, muſt be admitted, and of which the Somerſetſhire coal-mines deſcribed in the Philoſophical Tranſactions, N°. 360 and 391, by Mr. John Stracey, ſeem an inſtance; but in general it will be found, that the plane of the ſtrata beneath, conforms to any *regular plane* which is to be found on the ſurface, either of a hill or vale, excepting only in the firſt caſe, inſtances where a perfectly ſtraight and ſmooth fracture of the ſtrata has happened, and, in the latter caſe, where ſtagnant water has in times long poſterior to the formation of the ſtrata, made depoſits of mud, &c. in regular horizontal layers, or nearly ſo. This circumſtance is of the utmoſt conſequence to be attended to in tracing the ſtrata of a country, as alſo to note carefully the diſtinction between theſe original planes or facettes of a hill, and the curious curving ſurfaces occaſioned by the ending of ſtrata, or the leſs regular curving of the ſurface, occaſioned by the fracture (generally oblique or hading) and ſubſequent abraſion or rounding of the top and edges of the ſtrata by the action of moſt violent currents of water. The circumſtance mentioned by our author, of the ſtrata dipping into a hill, is obſervable at the endings of moſt of the ſtrata, and on the ruptured ſide of a large portion of hills and mountains, where the break or fiſſure occaſioning the hill was in the run or courſe of the ſtrata, as it lies at preſent, which, according to the obſervations of Charpertier, p. 80, is very generally the caſe; but where the preſent dip is in the direction of the fiſſure, or is inclined in any acute angle thereto, the ſtrata will croſs the riſe of the hill, direct or obliquely as the caſe may be.

The probability will be ſhewn hereafter, that ſome of the diſturbances, or ruptures in the ſtrata, have been confined to a certain number of the upper ſtrata, without affecting thoſe below, and hence regular ſtrata may ſometimes be found, under thoſe which are broken and uneven, as mentioned in this ſection; and the Somerſetſhire coal ſtrata above mentioned may perhaps thus be accounted for. We have never been able to diſcover any thing, in the upper or under ſurface of a ſeam of coal, which demonſtrates its having originally been ſoft, as mentioned § 21°; the gliſtening appearance of the ſurface in ſome partings, ſhews only the great regularity and truth of the planes or lamina, in which the ſtrata were at firſt depoſited. The poliſhed or rather rubbed ſurfaces of the ſlips or dykes in coal mines, and indeed in the ſtrata generally, is a circumſtance which ſeems moſt ſurpriſingly to have been overlooked by writers on this ſubject. Mr. Kirwan only gives it the curſory notice contained in § 21°. This rubbing ſeems to have ariſen from violent mechanical preſſure, and motion to and fro againſt each other, and this ſeems not confined to fiſſures or joints, where the ſtrata are lower on one ſide than on the other, ſo as to be explicable, as the effect of the ſlip, or mere ſinking down of one part, when in cloſe contact with the other; but this apparent wear in the ſurfaces, of even the ſmaller fiſſures, is as obſervable in marl and chalk pits, and all tolerably ſoft ſtrata, where no alteration of the level of the ſtrata has taken place, as where ſuch depreſſion of one ſide of the fiſſure is viſible. See Philoſophical Magazine, vol. xxv. p. 45 and 46, and vol. xxviii. p. 120. See alſo *Elevation of* STRATA. The facts and obſervations of Mr. Kirwan on coal, in ſections 23° to 25° above, agree with our remarks under the article COAL, on the unequal and apparently accidental diffuſion of the wood-like ſubſtances which have formed the ſtrata, or rather accumulations of wood-coal. That ſlips or dykes have never been obſerved in wood-coal mines, (§ 26°), can only, we think, have ariſen, from the limited extent of theſe accumulations in the ſtrata, at leaſt of ſuch as are worked; while the excavations in the planes of the ſtrata, as well as vertically in ſhafts, have been incomparably greater in the proper coal diſtricts, than in any other, and therefore it is, that the dykes &c. have there been beſt aſcertained; and from coal-working it has been, that almoſt all our knowledge of the ſtrata has been derived; they were the objects which firſt awakened Mr. Smith's attention to the ſubject of the ſtratification, and by obſervations in the next moſt extenſive field for theſe obſervations, *viz.* the cutting of navigable canals, he was enabled to generalize and extend the important facts, at preſent ſo little known, but to coal-miners, within their own particular diſtrict.

Genuine coal is now very ſeldom worked at its out-crop, as before obſerved, owing to the ſuperior quality of the ſame ſeam, when deeper covered; but wood-coal is generally worked ſo near to the ſurface, as to be opened at top, or uncallowed, inſtead of being mined for; it is no wonder therefore that gravel has been obſerved in contact with it, as obſerved § 27°.

Perhaps the ſpecimen mentioned § 28°, did not contain genuine coal in its cells; we conjecture this, from having ſeen ſpecimens of a reddiſh ſoft ſand-ſtone, which Mr. Farey brought laſt ſummer from the foot of the cliff on the ſea beach, about two miles eaſt of Haſtings in Suſſex, from the vicinity of a cottage called the Grovers, which contained ſo many detached pieces of bitumenized wood, that were an augre-hole to be bored into it, and ſupplied with water, &c. ſomething like the appearance of penetrating a coal vein, might be had in the borings; and it is this ſtratum, dipping under Bexhill, ſituate about 6½ miles to the weſtward, which in the opinion of Mr. F. has been there miſtaken in the borings for a ſeam of coals, but which the improved boring apparatus of Mr. Ryan, mentioned under COAL, would have detected, and ſaved, perhaps, a moſt unparallelled waſte of money, in the meaſures now purſuing.

The remark in § 29°, that genuine coal is ſeldom found in plains, is by no means true; the coal-ſtrata about Bedworth in Warwickſhire, Whibſey Slack near Bradford in Yorkſhire, and numerous other places which we could mention, form extenſive plains; a contrary remark to the above, would perhaps be much nearer to the truth.

It will readily be gathered, from our remarks on § 12°, that we have our doubts, on the diſtinctions between reſiniferous and non-reſiniferous plants, land and marine vegetables, and river and ſea ſhells, as accompaniments of coal, § 30 and 31, and that we incline to the opinion, that further ſearches will claſs all or moſt of them among the incognita of a prior ſtate of aquatic exiſtence.

Impreſſions from below the ſtrata § 33, eſpecially from elaſtic fluids, muſt have formed conic elevations or craters in making their eſcape, and could not have produced that univerſal breaking of the ſtrata which we find; which is indeed ſo univerſal, that a ſingle acre of the ſurface can ſcarcely be found

found without one, and sometimes numerous fissures through it, although the original plane of the strata is still maintained by its fragments, facts which had a material influence on the writer's reasonings upon this subject, which we have hinted at above. The seven following sections being stated, as consequences of Mr. Kirwan's particular tenets, which we shall mention presently, on the origin of coal, we shall pass them without comment for the present, and proceed to state the principal among the various opinions which have been given, on the origin of the invaluable substance, which is the subject of our present inquiry. In stating the opinions which have been held as to the origin of coal, we shall begin with that of Arduino and some others, who have supposed coal to originate from the fat and unctuosity of the numerous tribes of animals which have peopled the ocean; which matter being accumulated on the bottom of the sea, became covered by various strata, in consequence of the different changes which the surface of the earth and bottom of the seas have undergone. The most obvious objections to this hypothesis arise, from the total dissimilarity of coal to animal fat, and the levity of the latter compared with water, which should have occasioned it rather to rise to the top of the water and float, than to dispose itself in such extremely regular beds at the bottom, as to form strata of coal. The existence of a few shells in or near to coal, in some places, which resemble some of the recent sea shells, we conceive to be as far from proving it to be of marine origin (as contended by the author of this hypothesis) as the supposed resemblance of ferns, reeds, rushes, &c. and land and river shells, with the absence of bones of fish and sea salt in other places, proves it to be of land origin, § 30 and 31 of Mr. Kirwan's observations above, and Geol. Ess. 323.

The next opinion which we shall mention is that of M. Gensanne and others, who, from the specific gravity and hardness of some kind of coal, and its large quantity of bituminous matter, have concluded pit-coal to be a peculiar earth of the argillaceous genus, penetrated and impregnated with petroleum. To this opinion Mr. Kirwan opposes the remark in the 22° § above, and adds, that some known species of coal, that of Kilkenny for instance, contain no petrol or other bitumen in their composition, and are thence called natural carbon. See Mr. Kirwan's Mineralogy ii. 49.

M. Tingry, Dr. Darwin, and others, have imagined, that heat generated by the fermentation of immense beds of vegetable matters, have distilled or separated there from the oils, naphtha, asphaltum, &c. which condensed between the strata, and have formed seams of coal, and bituminous schists. On this fanciful theory it can scarcely be necessary to comment.

Dr. Hutton imagines coal to be formed by the slow depositions of oily and bituminous matters at the bottom of the sea, which matters he supposes to have originated in the dissolution of the various animal and vegetable bodies, which are continually perishing on the surface of the earth, and in the waters of the ocean. The fuliginous matter which is separated during the combustion of various bodies on the surface of the earth, he supposes, is washed off the surfaces on which it falls by the rain, and, being thus made to flow into the rivers, is carried off by them into the sea; where it also adds, by its deposition, to the mass which is accumulating at its bottom. Another source whence he supposes this matter to be derived, is the water draining from peat mosses, which, according to his ideas, is charged with bituminous matter, very much resembling fossil coal, when precipitated. The depositions of these matters in the sea are supposed by the Doctor to be so regular, as to produce strata, which, becoming covered by an immense weight of superincumbent earth, must thereby become exceedingly compressed and condensed, and finally consolidated, by the powerful influence of subterranean heat; and ultimately, by the progressive change of sea into dry land, these become seams of coal, such as we now find in the bowels of the earth. Granting that oily and bituminous matters are thus conveyed by the rivers into the sea, but which Mr. Kirwan has shewn does not take place, there is a manifest absurdity in supposing these matters to sink to the bottom of the water; while it is scarcely possible to conceive, that distinct beds or strata of coal and earth; especially such regular and extended ones as we find of them, can be formed by deposition in an ocean constituted as our present one is. The operation of heat upon these coal strata has been shewn by Mr. Kirwan and others, to be inconsistent with all the circumstances attending them. It is true that sir James Hall (Transactions of the Royal Society of Edinburgh, vol. vii.) has endeavoured to remove the force of these objections, by shewing, in the detail of his chemical experiments, and by the specimens presented to the British Museum in June 1806, that wood, or even horn, may be converted to a substance resembling coal, by the action of an intense heat applied under a very immense pressure. Valuable and satisfactory as we think sir James's experiments to be, in proving the possibility of carbonat of lime being fused without decomposition, and of vegetable and animal substances being melted or reduced to a coal-like substance, under the heat and confinement, as well as pressure which he applied, yet we think, the difficulty of Dr. Hutton and other Plutonists to be still nearly as great as ever in shewing, that such a degree of heat ever has existed in strata, not obviously volcanic; certainly, lava, however hot we may admit it to have been, could never by its mere protrusion under beds of sea-shells, as sir James Hall endeavours to explain, in his imaginary section of a volcanic mountain and adjoining sea, (*fig.* 41. in the Transactions,) have heated their whole mass, in the degree which his own experiments have shewn to be necessary for the formation of lime-stone; nor is it conceivable, that the supposed superincumbent strata, much less any depth of water, could have so effectually retained the carbonic gas, as he himself has shewn to be necessary, to form lime-stone or marble out of shells or chalk; or the other gasses, so as to effect the conversion of wood and vegetables into pit coal.

The ingenious Mr. Kirwan supposes, that a large class of primeval rocks and mountains, containing carbon and petrol in their composition, have been either totally destroyed, or their heights and bulk considerably lessened by disintegration and decomposition; and that by the equable diffusion of the disintegrated particles, successively carried down by the gentle trickling of the numerous rills that flowed from those mountains, the seams of coal and their attendant strata were formed, in lakes at their feet, we suppose, but this circumstance it is difficult to gather from Mr. K's account; according to which, the decomposed feltspar and hornblende formed clay, the particles of bitumen were set free, and these, when united, sunk through the moist pulpy, incoherent, argillaceous masses, and formed the seams of coal beneath them. Mr. Parkinson (Organic Remains I. 248.) has commented on the absurdity of such a light substance as bitumen, being supposed to descend through a pulp of argillaceous matters, and deposit itself in a stratum below it.

The next hypothesis which we have to mention, and which has numerous adherents, ascribes the formation of coal to forests of antediluvian trees, and to peat bogs, and other vegetable productions of the dry land of that period, buried during the supposed violences of the Mosaic deluge, under the strata which are found covering them

them in the ſtate of coal at this day. This hypotheſis we ſhall examine, and ſtate ſome of the objections to which it ſeems liable; and firſt, they are mines of wood-coal, deſcribed in §s. 23° to 29° above, which alone have the appearance of being formed by depoſitions of floating wood and other matters, in the irregularity of their extent, and the variable thickneſs of the ſeam, circumſtances extremely rare in regular coal-ſeams, or in the matters alternating with them. Some, we are aware, have contended, that this uniformity in the thickneſs of regular coal ſeams has ariſen, from the maſs of depoſited wood and vegetables having, ſince they were covered by the ſuperincumbent ſtrata, been liquified, or nearly ſo, by ſome proceſs, the exact nature of which has never been agreed upon by the advocates of this hypotheſis, and that in this ſoft ſtate (§ 21° above) they were preſſed into an uniform ſeam, or continued ſtratum. An obvious objection to this explanation, of the uniformity obſerved in the thickneſs of a real coal-ſeam ariſes from the fact, that all coal-ſeams preſent themſelves at the ſurface in the endings of the ſtrata, and frequently alſo in the ſides of hills, occaſioned by diſlocations of the ſtrata (§s. 19° and 41°); and here it will be difficult, if not impoſſible, to conceive, how the coal, when in a ſoft ſtate, was prevented from ſqueezing out by the weight of the ſuperincumbent ſtrata, and forming maſſes of that ſubſtance at the ſurface, of which no traces are obſervable; for, the diffuſion of the withered coal or ſmut, below the out-crop of coal ſeams (§ 41) has no ſuch appearance, but in all its circumſtances agrees, with the withered remains or rubble of other ſtrata at their outcrop. We incline to the opinion, that real wood, or other recent vegetable ſubſtances, have never been found in the coal ſeams, or in their accompanying meaſures or ſtrata: a large portion of the bitumenized vegetable impreſſions there found certainly bear no reſemblance to known woods, or plants of the preſent race; while moſt, if not all of ſuch remains, that have been denominated after recent plants, have been ſo named without that care which a botaniſt would exerciſe, in claſſing or naming a new recent plant which was preſented to him for examination. Hence the ſuppoſed reſemblance to land plants, rather than to aquatic plants in theſe curious remains, has, as we conceive, ariſen. Our next objection to the above hypotheſis is founded, on the improbability of the accumulation of ſuch immenſe quantities of trees and vegetable matter in the antediluvian world, in leſs than 17 centuries, when more than 42 centuries ſince have accumulated ſo little: if they had remained on the ſurface of the dry land and not decayed, a very large portion of the earth muſt have been thereby incumbered and rendered unfit for the habitation and uſe of men or animals; it is highly improbable, that they were progreſſively removed from the dry land to the antediluvian ſea, and there preſerved until the deluge. The probable quantity of growing trees and vegetables exiſting at the commencement of the Moſaic deluge, ſeems quite inſufficient to account for even the Britiſh coal ſtrata, when it is conſidered how much the bulk or maſs of the vegetable matter has, in all probability, been reduced, by its converſion into real coal: and this laſt ſuppoſition is alſo denied us, by the Moſaic account of this event, from which (Geneſis, vi. 7. 17. 19. 20; vii. 2, 3, 4. 8, 9. 14. 21, 22, 23; viii. 11. 17. 19; ix. 3. 20.) we gather, that the exiſting trees and vegetables (as well as fiſh) were not deſtroyed by the deluge. (See DELUGE.) Some writers on the formation of coal have ſpoken of it, as the remains of vegetable matters, either growing in, or that were depoſited in the ſea, in very diſtant periods, and which have been immured under layers of earth, &c. by certain convulſions and deluges (whether the Moſaic or others, ſome of them have not explained) which have ſince occurred: inſuperable difficulties will, we apprehend, be found to attend any hypotheſis, which ſuppoſes the burial of the matters compoſing coal, at any period ſince the earth has been divided into ſea and dry land as at preſent, let the origin of thoſe matters be ſuppoſed whatever they may.

The writer of this article begs leave to ſtate another opinion, which the recent diſcoveries of Mr. Smith and himſelf ſeem to render, in his judgment, moſt probable, on the origin of mineral coal. This writer has ſeveral times taken occaſion to mention the probability, that the ſurface of the earth, and as far below it as concerns us at preſent to conſider, originally conſiſted of parallel laminæ of different matters, not concentric to the earth, but inclined, or dipping towards the eaſt, and ending towards the weſt; each ſucceeding lamina, in aſcending the ſeries, being generally ſhorter towards the weſt than the eaſt, in the ſame manner as the very minute laminæ of cryſtals are now admitted to be, and thereby to form the ſlope, or inclination of the cryſtalline ſurface; but with theſe differences, that the laminæ of the earth, or the different ſtrata were diſpoſed to form indented or fingered endings, inſtead of the ſtraight lines ſo generally aſſumed in cryſtals of a ſmall ſize, and that the terreſtrial laminæ are of very unequal thickneſſes. Various circumſtances, beſides the immenſe maſſes of unbroken ſhells and other matters nearly ſimilar to the ſea ſhells, corals and other marine productions of the preſent time, ſhew theſe ſtrata to have been depoſited under quieſcent and probably very deep water, anſwering, as he conceives, to the ſtate of the earth as deſcribed by the ſacred hiſtorian, prior to the ninth verſe of the firſt chapter of Geneſis, or in the two firſt grand periods metaphorically called days, after which God ſaid "Let the waters under the heavens be gathered together into one place; and let the dry land appear." Abundant evidence will, as he apprehends, be furniſhed by an examination of the various organic remains lodged in or between the ſtrata, that the animals, at leaſt thoſe of the teſtaceous, cruſtaceous, and zoophytic kinds, whoſe remains they are, lived in the particular places where each is now found, at the time that the ſtrata, on or in which they are lodged, formed the bottom of the univerſal ocean above-mentioned; each newly depoſited ſtratum being a proper nidus for the production, and probably a pabulum for the nouriſhment of the animals peculiar to it, and which apparently in moſt inſtances ceaſed to exiſt, when new matter in proceſs of time began to be precipitated, for the production of a new ſtratum upon the former one, which, alſo, in turn had its own peculiar animals, as their remains in ſuch numerous inſtances teſtify.

The opinions of that able naturaliſt, M. Cuvier, in his recent report to the national inſtitute of France on the tranſactions of that learned body in 1806, are in favour of the animal incognita of the ſtrata, having lived where their bones are now found: and from an examination of the accounts from more than 600 places, where bones reſembling thoſe of elephants and rhinoceroſes have been dug up, belonging principally to the claſs of *gravel foſſils*, we believe, this able anatomiſt is of opinion, that all theſe differ eſſentially from the recent animals of theſe kinds and are of ſpecies now quite extinct.

Apparently, after long periods of ſucceſſive depoſition and animal exiſtence, ſuch ceaſed for a time altogether, or nearly; and the ſtrata produced an immenſe variety and quantity of vegetables, moſt of them quite unlike the vegetable tribes of the preſent race; the immenſe foreſts of of weeds which have been difcovered at the bottom of the prefent ocean, in fome places, probably bear no proportion to the thicknefs and magnitudes of many of thefe vegetable productions of the primitive or univerfal ocean, as fome of them probably exceeded our trees in fize; their arboriferous trunks, fo clofely imitating wood, as not hitherto to have been diftinguifhed therefrom; but the greater part of the vegetables appear to have been of a fmall fize, efpecially on ftrata, which feem to have been depofiting fo faft as to have immured them fingly, as is often the cafe with the bituminous or coal fhales, mentioned under COAL, of which the moft beautiful, various, and minute fpecimens, might be obtained in many coal workings. The fucceffive depofitions in thefe vegetable, or carboniferous foils, appear to have differed, as we have ftated thofe of the animal, or epizootic, to do, in their fitnefs for producing different kinds, and a fimilar appearance and difappearance of different vegetable remains will be obferved, in examining a feries of coal meafures, or ftrata, upwards or downwards; and, often, ftrata will be found intervening fuch, which contain no vegetable impreffions, but in fome rare inftances, thofe of animals will therein be found, which obfervations, of too limited an extent, as we fufpect, have denominated land and river exuvia, § 12° and 30° above.

It is to beds of fub-aqueous vegetables, fuch as have been mentioned above, uniformly and thickly covering large extenfions of the planes of ftrata, if not their whole extent, that the writer of this article can alone look, in his view of the fubject, for the true origin of vegetable coal; and according, perhaps, to the nature of thefe vegetables, as well as to the kind or quantity of the mineral depofits, made during their growth, will the quality of different feams of coal be found to vary, while their different thickneffes has depended, on the quantity of vegetable matter accumulated, either dead, as in our peat bogs, or then actually growing, when a depofition began to happen, either fo copious or different, as to put a period to their growth, and ultimately to immure them. That vegetable impreffions are rarely found in the fubftance of a coal-feam, as remarked by Mr. Kirwan in the paffage (§ 12°) above quoted, may, we think, be perfectly accounted for, when the peculiar kind of cryftallization, which all good mineral coals feem to have undergone, is taken into confideration; a change which feems to have effectually deftroyed the organization of the plants compofing the coal, but without a liquefaction having happened, as in fome ftony cryftallizations, which have of late years been noticed by mineralogifts.

Mr. Parkinfon endeavours to account for this change, which vegetable matters undergo in paffing into coal (Organic Remains, p. 253.) by a procefs which he calls *bituminous* FERMENTATION, which fee. According to the obfervations of this gentleman, foffil coal has alfo, in this change, had numerous fepta, or thin fibres of uninflammable matter, interpofed between the particles of pure bituminous matter, of which it principally confifts, which has modified its inflammability in the degree which renders pit coal fo well fitted for the purpofes to which it is applied. In the fpecimens which Mr. P. examined, the inclofed particles of bitumen were in form of rhomboids, or parallelepipeds, and the feparating pellicles, or fepta, were formed of fulphate of lime, containing a fmall portion of alumine, and fometimes of fulphuret of iron alfo. Organ. Rem. 269.

The new opinions which we have ventured to prefent, if fuch they are, relating to the origin and formation of coal, in that and the prefent article, will, as we truft, be candidly received by our readers, and fubmitted to that fovereign teft, an unprejudiced comparifon with the phenomena, by which it is our fincere wifh that they fhould either ftand or fall, as it is alfo of the gentlemen above alluded to, through whofe valuable labours and communications, we were enabled to give them.

The moft remarkable colliery, or coal-work, that we have ever had in this ifland, was that wrought at Burrowftonenefs, under the fea. The veins of coal were found to continue under the bed of the fea in this place, and the colliers had the courage to work the vein *near half way over*; there being a *mote* half a mile from the fhore, where was an entry that went down into the coal-pit, under the fea. This was made into a kind of round key, or mote, as they call it, built fo as to keep out the fea, which flowed there twelve feet. Here the coals were laid, and a fhip of that draught of water, could lay her fide to the mote, and take in the coal.

This famous colliery belonged to the earl of Kinkardin's family. The frefh water which fprung from the bottom and fides of the coal pit, was always drawn out upon the fhore by an engine moved by water, that drew it forty fathom. This coal pit continued to be wrought many years to the great profit of the owners, and the wonder of all that faw it; but, at laft, an unexpected high tide drowned the whole at once, and the labourers had not time to efcape, but perifhed in it. Phil. Tranf. No. 98.

COLLIGAT, in *Ancient Geography*, a town of Ethiopia near Egypt, feated on the bank of the Nile, according to Pliny.

COLLIMATION *of a Telefcope*, in *Optics*, is that line which paffes through the tube, and cuts both the focus of the eye piece and alfo the centre of the object glafs; the derivation of the term is from *col*, *con*, or *cum*, *with*; and *lima*, *a file*, in confequence of the exactitude with which it ought to be adjufted, at right angles to the axis of a telefcope, that is moveable on pivots in any aftronomical inftrument. It is in this line that the middle wire of the eye-piece ought to be exactly placed, in any telefcope for celeftial obfervations; which pofition may be afcertained by reverfing the ends of the axis, and noticing, in both fituations, a point in a diftant object that is bifected by the faid wire; the deviation from true bifection being always double to the error in collimation, when the line of collimation is at right angles to the axis of motion of the telefcope. The lateral fcrews of adjuftment, at the focus of the eye-piece, in the beft inftruments, will readily bring the middle wire into the true line of collimation with but little trouble.

COLLINS, JOHN, in *Biography*, a mathematician of confiderable eminence, was born at Wood Eaton, in Oxfordfhire, in March 1624. He was educated by his father, a diffenting minifter, and at the age of 16 was bound apprentice to a bookfeller at Oxford, but foon after the beginning of the civil wars he was made a junior clerk of the prince of Wales's kitchen. In this fituation he was under the fuperintendence of Mr. Marr, a good mathematician, and famous for the dials with which he adorned the gardens of king Charles. From hence young Collins embarked in the fea fervice, and having already made fome progrefs in mathematical

mathematical purſuits, he employed all his leiſure time in improving himſelf in the practical branches of ſcience. Upon his return to England he taught mathematics, and in the year 1652 publiſhed an "Introduction to Merchants Accounts." From this period he frequently preſented the public with treatiſes in various departments of ſcience, which were all well received, and to a certain degree popular. In 1667 Mr. Collins was made accountant to the Exciſe Office, and choſen member of the Royal Society. He had not been long a member of this learned and reſpectable body, when he laid before it ſome papers on the ſubject of chronology, and in 1699, a diſſertation of his was publiſhed in the "Tranſactions," on the reſolution of equations in numbers, in which are ſeveral important hints on the doctrine of differences, and other topics. He was nominated by lord Shafteſbury in divers references concerning ſuits in Chancery, to aſſiſt in ſtating intricate accounts; and was ſoon after appointed accountant to the Royal Fiſhery Company. Mr. Collins, by many publications, ſhewed how deeply he was verſed in the principles of trade and commerce. His works are numerous, and they diſplay the features of a liberal mind and a clear head. Beſides thoſe already noticed we have treatiſes on the "Mariner's Plane Scale," on "Geometrical Dialling;" on "Arithmetic;" on "The Quadrant;" on "Salt and Fiſhery," and divers papers in "The Philoſophical Tranſactions." Mr. Collins was a great promoter of the works of others, and the world is indebted to him for Barrow's "Optical and Geometrical Lecture;" his edition of "Archimedes;" and of "The Conics of Apollonius;" "Wallis's Hiſtory of Algebra," and many other excellent works. He died in London, November 1683, of conſumption, produced it was thought by drinking cyder while he was hot from great exerciſe. His papers were, after ſeveral years, put into the hands of Mr. William Jones, F. R. S., and it was from theſe that the claims of ſir Iſaac Newton to the invention of fluxions was eſtabliſhed, in the "Commercium Epiſtolicum D. Johannis Collins, et aliorum, &c." Mr. Collins was indefatigable in the purſuit of uſeful truths, and ſpared no pains in the promotion of real ſcience. Natural knowledge is greatly indebted to him, for while he excited ſome to publiſh uſeful inventions, he employed others to improve them; but his own merit was not ſufficiently rewarded by thoſe who had the means of patronizing him. Biog. Brit.

Collins, Richard, an engraver, native of Luxemburgh, who ſtudied at Rome at the ſame time with Sandrart, and engraved ſeveral plates for his work entitled "The Academy." Upon his return from Italy he eſtabliſhed himſelf at Antwerp, and ultimately at Bruſſels, where he aſſumed the title of engraver to the king of Spain. According to an inſcription copied by Heinecken from one ſurrounding his portrait, he was born in 1627. The dates on his prints are from 1664 to 1685. He made ſeveral indifferent engravings of portraits, as well as other prints from the pictures of Rubens, Murillo, S. Bourdon, and others. Heinecken.

Collins, Samuel, doctor in medicine, was educated at Cambridge, and made fellow of King's college in that univerſity. In 1650 he was admitted of New college in Oxford, by favour of the viſitors, Anthony Wood ſays. He ſoon after went to Ruſſia, and reſided at the court of the czar for nine years. On his return to England he was made fellow of the Royal College of Phyſicians in London. In 1671 he publiſhed a "Hiſtory of the Preſent State of the Court of Ruſſia, in a Letter to a Friend," illuſtrated with engravings, and in 1685, "A Syſtem of Anatomy, treating of the Body of Man, Beaſts, Birds, Fiſh, Inſects, and Plants," with numerous figures drawn from the life, 2 vols. folio. In the comparative anatomy, incomparably the moſt valuable part of the work, he received much aſſiſtance from Dr. Edward Tyſon, particularly in the anatomy of fiſhes and birds, in which he excelled. "Nemo Collino melius de ea eſt meritus," Haller ſays. The work is now, however, little noticed. There is a beautiful head of Collins, drawn and engraved by Faithorne, which gives it value to collectors of prints. Wood's Faſti Oxon. Haller's Bib. Curat.

Collins, John, an engraver of Antwerp, who ſpent ſome time in Rome, and afterwards, according to Mr. Strutt, reſided in England. There are ſome indifferent portraits by this artiſt, one of which, repreſenting Keay Nabe Naia Wi-praia, principal ambaſſador from the Sultan Abdulcahar, king of Suroſoan, is dated 1682. He likewiſe engraved the "Funeral Proceſſion of George, Duke of Albemarle," and ſeveral other prints from various maſters. Other artiſts of the name of Collins are mentioned by Heinecken.

Collins, Anthony, a writer of conſiderable eminence, was born at Heſton, Middleſex, on the 21ſt of June 1676. He was educated in grammar learning at Eton, and from thence he was removed to King's college Cambridge, under the tuition of Mr. Hare, afterwards biſhop of Chicheſter. When he quitted the univerſity he entered himſelf a ſtudent in the Temple, but, diſguſted with the purſuits of the law, he quickly relinquiſhed all thoughts of that profeſſion. In 1698 he married, and being poſſeſſed of conſiderable property, devoted himſelf to literary purſuits. In 1703 and 1704 he maintained an epiſtolary correſpondence with the celebrated Mr Locke, who conceived for him a very high regard, and in 1707, he publiſhed his "Eſſay concerning the Uſe of Reaſon, &c." a work containing many valuable obſervations, but which diſcovered ſtrong prejudices againſt divine revelation. About the ſame period Mr. Collins engaged in the controverſy carried on by Mr. Dodwell and Dr. Clarke, concerning the natural immortality of the ſoul. See Clarke. In 1709 he publiſhed "Prieſtcraft in Perfection, &c." and other controverſial pieces; and in the following year "A Vindication of the Divine Attributes," in anſwer to a ſermon, by the archbiſhop of Dublin, on "Divine Predeſtination, conſiſtent with the Freedom of Man's Will." He ſpent a conſiderable part of the year 1711 on the Continent, where he cultivated the acquaintance and regards of M. Le Clerc and other men of eminence. In 1713 he publiſhed "A Diſcourſe on Free Thinking," in which he vindicated the univerſal right of unlimited freedom of inquiry, and expoſed the tyranny exerciſed by the abettors of prieſtcraft; this was the profeſſed object of the work, but the author's ſecret intention was undoubtedly to attack revealed religion; it therefore called forth ſome able replies from Mr. Whiſton, Dr. Hoadly, and Dr. Bentley. Mr. Collins now paid another viſit to Holland, and from thence he proceeded to Flanders, in both which countries he was received by men of letters with the moſt marked attention. On his return he ſettled in the county of Eſſex, where he exerciſed the important duties of magiſtrate and deputy lieutenant of that county. About the year 1715 he publiſhed his "Philoſophical Inquiry concerning Liberty," which is unqueſtionably one of the beſt treatiſes on that ſubject; it is highly methodical and very conciſe, and its illuſtrations are ſimple and perſpicuous. On this ſmall tract Dr. Clarke made ſome remarks, of which Mr. Collins took no notice. In the year 1718 he was choſen treaſurer of the county, an office which he executed

executed with exact fidelity, to the great relief of numerous claimants on the county rates. In the year 1724 he published an "Historical and Critical Essay on the Thirty-nine Articles," and a "Discourse of the Grounds and Reasons of the Christian Religion;" this last work, being an evident attack upon Christianity, was answered by many of the leading men of that day, both of the established church, and among the dissenters. His work entitled "The Scheme of Literal Prophecy," &c. called forth also the pens of some able advocates for the truth of revelation, and it may be safely affirmed that the controversies excited by Mr. Collins redounded to the honour and firm establishment of the cause which he hoped to undermine. After a life of activity, in which his talents had been frequently and zealously employed for the advantage of his countrymen, Mr. Collins died of a severe attack of the stone, a disorder which had for some years been sapping away the principles of his constitution. As a writer his works will speak for him, some of which, besides his "Inquiry concerning Human Liberty," are still held in considerable estimation. As a man, his moral conduct was exemplary for the virtues of temperance, humanity, benevolence, and patient industry. In the exercise of his magisterial functions he was active, upright, and impartial, and in domestic life he was a tender husband, a kind parent, a good master, and a true friend. In the cause of true liberty he was an ardent votary, and whatever his particular sentiments might be on certain topics, he appears to be sincerely attached to the investigation of truth, so that on his dying bed he could appeal to his maker for the rectitude of his intentions, declaring that he had always endeavoured, to the best of his ability, to serve his God, his country, and his sovereign. By some of his contemporaries, and some of those who engaged in controversy with him, he was charged with atheism, for which there seems to have been no foundation. It must be admitted that he paid little regard to accuracy in the mode of his quotations, adapting them, without scruple, to his own purposes, however contrary they might be to the meaning of the authors cited, or the connection which the passages referred to stood. "So many facts" says the amiable Dr. Kippis, "of this kind were undeniably proved against him by his adversaries, that he must ever be recorded as a flagrant instance of literary disingenuity." Biog. Brit. Hollis's Memoirs, and Collins's different Treatises.

Collins, William, a poet of distinguished eminence, was born at Chichester in 1720 or 1721. His father, who carried on the trade of a hatter in that city, sent him to Winchester school, where he made considerable proficiency in the learned languages. From Winchester he went to Queen's college, Oxford, whence in 1741 he removed to Magdalen's. During his residence at the university he published his Oriental Eclogues which were not received by the public with any extraordinary favour. This circumstance did not, however, discourage him from relying on his pen for subsistence, and in 1744 he repaired to London in the character of a literary adventurer. Soon after his arrival in the metropolis he published proposals for a "History of the Revival of Literature," a work which he certainly never accomplished, and which in all probability was never begun. In 1746 he produced his "Odes Descriptive and Allegorical," which so little suited the taste of the day that their immediate sale did not indemnify his publisher for the expence of printing. Indignant at the insensibility manifested by the literary public to the merit of some of the finest compositions in the English language, and alarmed by the pursuit of his creditors, he secretly withdrew into the country. Not being sufficiently secure in his retirement he fled into Germany, when he put himself under the protection of his uncle, lieut. colonel Martin, who was with the army. On the death of that relation, which occurred soon after, Collins inherited by his will a legacy of 2000*l.* He now thought himself rich, and after honourably discharging his debts, resolved to live in decent retirement upon the remainder of his capital. But fortune favoured him at too late a period. The vexations which he had experienced in early life, and the occasional irregularities of his conduct, had gradually induced such a depression of spirits, that, though his intellectual faculties were unimpaired, he was utterly deprived of the power of exertion. After struggling in vain to overcome his malady by a journey into France, he became so much worse that his friends deemed it expedient for a time to confine him in an asylum for lunatics. Having derived some little benefit from the medical aid which was administered to him at this place, he was removed to Chichester, where his distresses were soothed by the tender assiduities of his sister, in whose arms he expired in the year 1756.

Thus short and melancholy was the career of a poet, who united in his compositions the brilliancy of a vivid imagination and the correctness of classic taste. The tardy justice of posterity has made amends for the contemptuous neglect of his contemporaties, and the poems of Collins are now acknowedged to abound in lofty flights of fancy, and in the most touching expression of a feeling heart.

Collins's *Quadrant.* See Quadrant.

COLLINSON, Peter, in *Biography*, an eminent naturalist and antiquary, was born January 14, 1693-4, most probably in London. He was of a quaker family, originally from Westmoreland. He carried on the business of a wholesale woollen-draper, or man's-mercer, in Grace-church-street, as his father appears to have done before him, and acquired an ample fortune. This enabled him, about the year 1740, if not earlier, to indulge in the luxury of a country house and botanic garden, situated at Mill Hill, in the parish of Hendon, ten miles north of London, as well as to gratify his prevailing taste by an extensive foreign correspondence, and the acquisition of specimens of natural history, and books, from various quarters. He very early obtained the notice and friendship of the most eminent naturalists and philosophers of his age and country, as well as of foreigners. Among the former are to be reckoned, Derham, Woodward, Dale, Lloyd, Sloane, and Ellis; among the latter, Klein and the celebrated Linnæus. Persons in a superior station to his own, treated him with familiarity and respect; as sir Charles Wager, through whose active exertions in the cause of natural science, at the suggestion of Mr. Collinson, innumerable exotic productions were, from time to time, brought to enrich the public and private museums of this kingdom; and the famous earl of Bute, whom he frequently visited at Caen wood, in his way to Mill Hill, and some of whose botanical letters to Mr. Collinson are in the hands of the writer of this article. With America he had many connections; and was long the principal channel through which the learned and scientific discoveries of Europe were conveyed to that rising country. He had the honour of communicating to the great Franklin the first knowledge of the electrical discoveries of that day. With Mitchell, Colden, and other American botanists, he maintained a constant correspondence, and had a principal hand in encouraging the indefatigable John Bartram in his botanical travels through the southern provinces of North America. Hence, as well as from the north of Europe, his garden derived ample supplies. At the time of his death, and even for 30 years afterwards, many rare American and Alpine plants, accommodated with every possible contrivance for shade, moisture, and a suitable exposure, were, in a manner, naturalized there, flourishing in the greatest luxuriance; till an ignorant and tasteless purchaser of this classical spot, rooted out its choicest treasures, and felled some of its finest trees, of species scarcely to be seen in perfection elsewhere. At length, however, it has found an owner who knows its value; and many flowering Cembra pines, with several American trees, are happily preserved from destruction.

In December, 1728, Mr. Collinson became a fellow of the Royal Society. Of the society of antiquaries he was a fellow from its first institution. The publications of both these learned bodies are enriched with his writings. He was also associated with the academy of Berlin; and, through the recommendation of his friend Linnæus, with that of Stockholm.

One of the inquiries, relating to natural history, which most interested him was the migration of swallows, for which he strenuously contended, in opposition to the opinion, as strenuously maintained by several other naturalists, of their remaining through the winter under water. At length, however, in a letter to Linnæus, dated September 15, 1763, he professes to be convinced by his illustrious correspondent that these birds do live under water all winter; subjoining nevertheless so many hints respecting the anatomical inquiries requisite to establish this wonderful fact, and so much dissatisfaction with what had hitherto been done, that he rather betrays the doubt than the conviction of his own mind.

Concerning antiquarian studies, certain round towers, in Ireland, of whose original use and design the learned are still doubtful, engaged his attention. But his most valuable communication in this line related to some Tartarian antiquities, described in the Archæologia.

Nor were Mr. Collinson's studies devoted merely to speculative or amusing objects. No philosopher ever combined utility with science more than himself. The management of sheep in Spain, of which he procured and published an account in the Annual Register, and Gentleman's Magazine, for 1764, given at length in the Biographia Britannica, is one of the most valuable documents of which we are possessed on that subject. All improvements in planting and gardening were studied and pursued by him with indefatigable zeal. His favourite luxury was fruit, and his passion, flowers. He writes with great complacency to Linnæus, the result of an observation made in his own garden, which proved the nectarine to be, as Linnæus had thought, a variety of the peach, a nectarine tree having sprung up at Mill Hill from a stone of the latter fruit. In the same letter, dated "Ridgway House, on Mill Hill, March 16, 1767," he thus details the progress of an English spring in the flower garden: "The hellebore, snowdrop, aconite, violet, &c. these," says he, "bloom in frost and snow, like the good men of Sweden. Then a tenderer tribe succeeds, and the garden is covered with more than 20 different species of crocus, *produced from sowing seeds*; and *iris persica, cyclamen vernum*, and polyanthos. Now plenty of *hyacinthus cæruleus* and *albus* in the open borders, and anemonies; and now *my favourites*, the great tribe of Narcissus, and polyanthos, shew all over the garden and fields. We have two species wild in the woods, that now begin to flower. Next the *tulipa præcox* is near flowering, and so Flora decks the garden with endless variety, ever charming. The progress of our spring to the middle of March, I persuade myself, will be acceptable to my dear baron." In the sequel of this letter, the last he ever wrote to Linnæus, he adverts to various subjects, not forgetting the swallows, and subscribes, "P. Collinson, now entered into my 73d year, in perfect health and strength of body and mind. God Almighty be praised and adored for the multitude of his mercies!"

His happy and useful life terminated on the 11th of August, 1768, in consequence of a suppression of urine, with which he was seized while on a visit in Essex, to his excellent friend lord Petre, a nobleman for whom, and for his father, both distinguished promoters of botany, Mr. Collinson had the highest regard. One of his letters to Linnæus is partly occupied with a long account of the character and pursuits of the last-mentioned lord, who died at an early age, in 1742.

Mr. Collinson married, in 1724, Mary, the daughter of Michael Russell, esq. of Mill Hill, with whom he lived very happily till her death, in 1753. He left issue, a son, named Michael, who resided at Mill Hill, and died a few years since, whose son is still living; and a daughter, Mary, married to the late John Cator, esq. of Beckenham, in Kent. Both his children inherited much of the taste and amiable disposition of their father. Biog. Brit. Fothergill's account of the late Peter Collinson. P. Collinson's MS. letters to Linnæus. S.

COLLINSONIA, in *Botany*, (so called in honour of Peter Collinson, F.R.S. a very active promoter of botanical studies, by whom the first species was introduced into the English gardens.) Linn. Gen. 40. Schreb. 51. Willd. 64. Lam. Ill. 51. Gært. 405. Juss. 112. Vent. ii. 331. Class and order, *diandria monogynia*. Nat. Ord. *Labiatæ*, Juss. Vent.

Gen. Ch. *Cal.* one-leafed, tubular, two-lipped, short, permanent; upper lip three-cleft; segments reflexed, broader; lower lip bifid; segments awl-shaped, more erect. *Cor.* monopetalous, unequal; tube funnel-shaped, many times longer than the calyx; border somewhat two-lipped; upper lip very short, four-toothed; lower lip very long, cloven into numerous capillary segments. *Stam.* Filaments two, bristle-shaped, erect, very long; anthers simple, incumbent, compressed, obtuse. *Pist.* Germs four, superior, three of them abortive, with a largish gland beneath them. *Style* bristle-shaped, the length of the stamens, inclined to one side; stigma bifid, acute. *Peric.* the permanent calyx. *Seed* one, globular.

Ess. Ch. Corolla unequal; lower lip with numerous capillary segments. Seed only one; three of the germs constantly abortive.

Sp. 1. C. *canadensis*. Linn. Sp. Pl. Mart. 1. Willd. 1. Cold. Noveb. 8. Kalm. It. ii. 317. Eng. Ed. i. 197. Lam. Ill. tab. 21. Gært. tab. 66. (C. serotina, Walt. Car. 65?) "Leaves egg-shaped, smooth; stems smooth." *Root* perennial. *Stems* three or four feet high, annual, erect, quadrangular. *Leaves* about six inches long, opposite, on very short petioles, acute, bluntly serrated, wrinkled. *Flowers* yellowish, numerous, peduncled, in panicled racemes with opposite ramifications. A native of North America. It has a peculiar, very strong, but agreeable scent; and is reputed to be an excellent remedy against pains in the limbs, occasioned by a cold, if the parts affected be rubbed with it; a decoction of it is also said to have cured the bite of the rattlesnake. In New York it is called horseweed, because the horses eat it in the spring before any other plant comes up. 2. C. *scabriuscula*. Mart. 2. Lam. Ill. 2. Willd. 2. Hort. Kew. i. 47. (C. præcox. Walt. Car. 65?) "Leaves somewhat

ſomewhat cordate-egg-ſhaped, rather hairy; ſtems ſomewhat hairy, ſcabrous." *Root* perennial. A native of Eaſt Florida, obſerved by Bartram, cultivated by Dr. Fothergill in 1776.

Propagation and Culture. The firſt ſpecies may eaſily be propagated by parting the roots in October. Theſe ſhould be planted three feet diſtant from each other in a warm ſheltered ſituation, and duly watered. With this treatment the plants will thrive in the open ground, and if regularly watered, will ripen their ſeeds in good ſeaſons. The ſecond ſpecies is more tender, and requires the protection of the green-houſe.

COLLIOURE, in *Geography*, a town of France, in the department of the Eaſtern Pyrenées, and chief place of a canton, in the diſtrict of Ceret, with a ſmall port on the Mediterranean; defended by a caſtle on a rock, and inhabited chiefly by fiſhermen. Near this town the Spaniards were defeated by the French in May, 1794; in conſequence of which the national convention decreed, that a column ſhould be erected as a memorial, that "7000 Spaniards laid down their arms before the republicans;" 5 leagues S.E. of Perpignan, and 5 E. of Ceret.

COLLIPO, in *Ancient Geography*, a municipal town of the Luſitanians, at ſome diſtance from the ſea, N. of Scalabis.

COLLIQUAMENTUM denotes a very tranſparent fluid obſervable in an egg two or three days after incubation, containing the firſt rudiments of a chick. It is incloſed in its own proper membrane, diſtinct from the *albumen*. Harvey calls it *oculus*.

COLLIQUATION, from *colliqueo, to melt*, in *Pharmacy*, the action of melting together two or more ſolid ſubſtances; or rendering them liquid by fuſion, or diſſolution; as wax, mucilages, &c. by heat; gums, &c. by moiſture.

COLLIQUATION is alſo uſed to expreſs ſuch a temperament, and diſpoſition of the animal fluids, as proceeds from a too lax compages; whereby they flow off through the ſeveral glands, and particularly through thoſe of the ſkin, faſter than they ought; which occaſions fluxes of many kinds, but moſtly profuſe, greaſy, clammy ſweats.

If this *colliquation* continue, it generally terminates in an hectic fever, and is uſually a concomitant of one.

The curative intention in this caſe is the giving a better conſiſtence to the juices by balſamics and agglutinants; and the hardening of the ſolids by ſubaſtringents. Hence,

COLLIQUATIVE *fever* is a fever attended with a diarrhœa, or profuſe ſweats, from too looſe a contexture of the fluids.

COLLISEUM. See COLISEUM.
